TUMOR PATHOPHYSIOLOGY AND THE RESPONSE TO RADIATION AND HYPERTHERMIA

ESR 3, AU: Folefac Charlemagne Asonganyi
Supervisor Prof: Michael Robert Horsman
Institution: Aarhus University Hospital

This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 955625. This website reflects only the author's view and the European Commission is not responsible for any use that may be made of the information it contains

SUB OBJECTIVES OF THE PROJECT

- Investigate the relationship between various tumor pathophysiological parameters on the interaction between radiation (**photons and protons**) and **hyperthermia**.
  - Use tumor and mouse models to determine the importance of the time interval between the application of radiation (SBRT) and heat (39-44°C). (**Mice model** -CDF1 & **Tumor type**-C3H mammary carcinoma).

    Establish the minimal, maximum temperature and the time interval needed to enhance radiation response with less toxicity.

- Perform mechanistic studies to understand this heat-radiation (SBRT) interaction
  - **Blood flow, oxygenation/hypoxia.**
  - **DNA repair, direct/indirect killing, and immune effect**).
- Investigate the potential of hyperthermia to be used as an **adjuvant for re-irradiation treatment.**
  - Understand the role of thermotolerance and step-down heating.

HYPERBOOST
Boosting the effect of Radiotherapy

HANDS ON TRAINING ON RELEVANT TECHNIQUES TO MY MAIN PROJECT

- Combining some existing antitumor therapists to treat different tumor sizes (50-400 mm3) of C3H mammary carcinoma.
  - Anti-Cytotoxic T Lymphocytes Associated protein-4 (anti-CTLA4) checkpoint inhibition (10 mg/Kg * 4) along with:
    - High single dose proton radiation (20 Gy)
    - OXi4503 Vascular Disrupting Agent (VDA) (50 mg/kg * 4)
    - Single thermal dose of Hyperthermia (42.5 Degree, 1 hr)

Priyanshu M Sinha, Folefac Charlemagne Asonganyi, Michael R Horsman.
(Paper in progress for publication).

HYPERBOOST
Boosting the effect of Radiotherapy

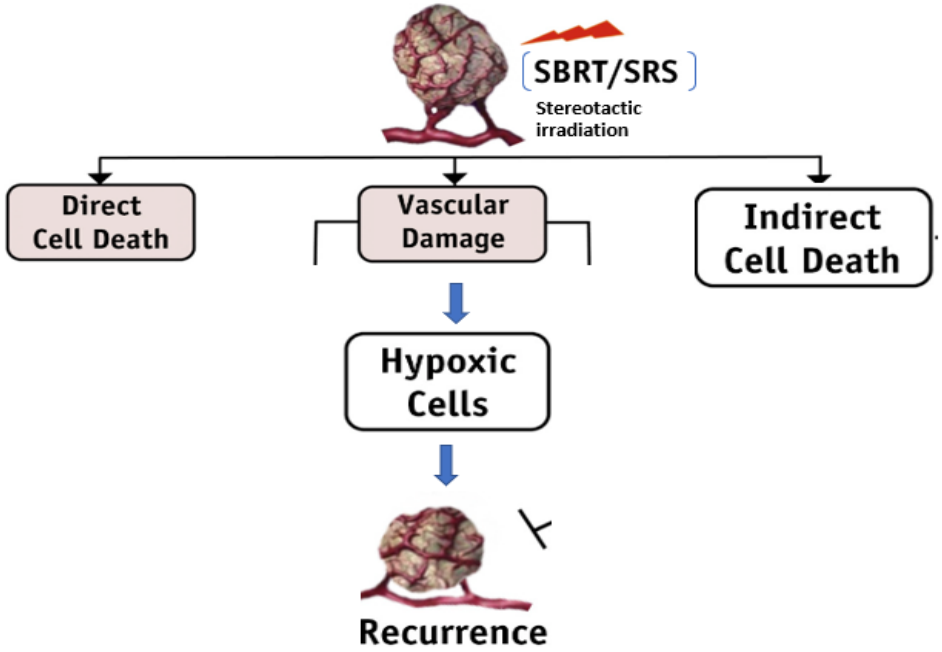
BACKGROUND

INVESTIGATE THE RELATIONSHIP BETWEEN TUMOR PATHOPHYSIOLOGICAL PARAMETERS ON THE INTERACTION BETWEEN RADIATION AND HYPERTHERMIA

EFFECTS OF SBRT RADIATION TREATMENT

SBRT/SRS

- Can kill cancer cells **directly** and **indirectly**.
- It can also destroy blood vessels which supply cancer cells, contributing to hypoxic cancer cells which may eventually leads to recurrence of primary tumor after treatment.

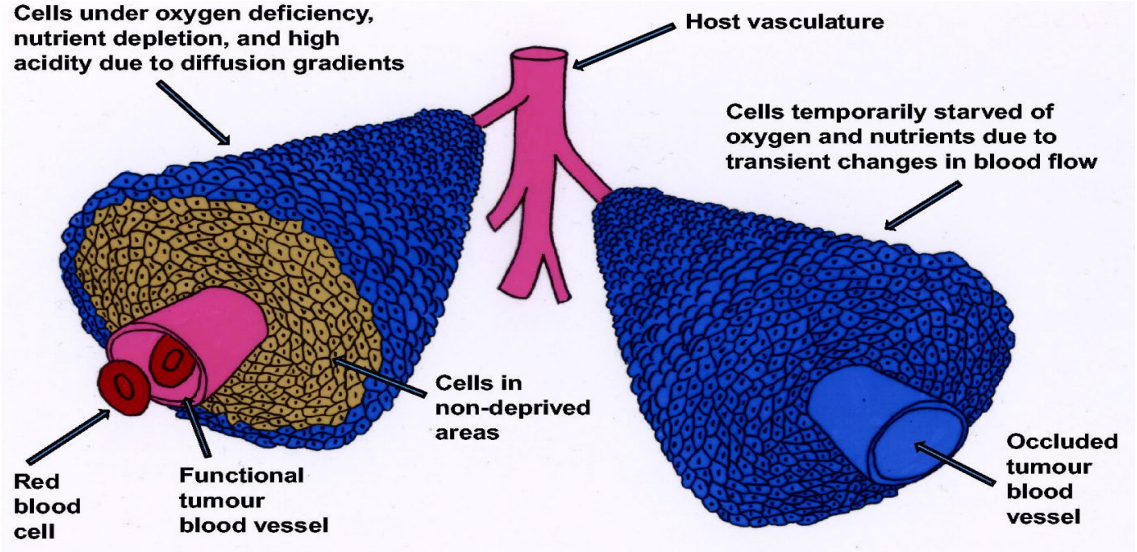


Adapted from Song et al., 2019. Biological Principles of Stereotactic Body Radiation Therapy (SBRT) and Stereotactic Radiation Surgery (SRS): Indirect Cell Death. Int J Radiation Oncol Biol Phys, Vol. 110, No. 1, pp. 21e34, 2021

HYPERBOOST
Boosting the effect of Radiotherapy

BACKGROUND

THE INTERRELATIONSHIP BETWEEN TUMOUR CELLS AND THEIR VASCULAR SUPPLY



Horsman MR, Mortensen LS, Petersen JB, Busk M, Overgaard J. Imaging hypoxia to improve radiotherapy outcome. Nat Rev Clin Oncol 2012;9:674–87

OTHER POSSIBLE EFFECTS OF SBRT ON TUMOR MICROENVIRONMENT

- Hypoxia (low oxygen) leads to radioresistance.
- Low glucose nutrients, low extracellular acidity, increase level of lactate acid.

➢ Cancer cells in these poor conditions can be kill with hyperthermia temperature (Overgaard J, 1989).

- Combining SBRT with heat can have therapeutic benefits.

Effects of heat:
Radiosensitization of cancer cells, enhancement of radiation (inhibit DNA damaged repair mechanisms) and direct hypoxic cell killing (A.L. Oei et al, 2020).

HYPERBOOST
Boosting the effect of Radiotherapy

BACKGROUND

- How should SBRT and hyperthermia be applied in order to obtain the most therapeutic benefits with less toxicity?
  - What hyperthermia Temperature? What SBRT fraction? What Time interval? What heating duration?

- What has already been done preclinically and what is currently been done in the clinic as far as **SBRT + Hyperthermia** is concern?

HYPERBOOST
Boosting the effect of Radiotherapy

PRECLINICAL AND CLINICAL STUDIES COMBINING SBRT + HYPERTHERMIA

- REVIEW ON THE RATIONAL FOR COMBINING SBRT AND HYPERTHERMIA (**ongoing**)

Folefac Charlemagne Asonganyi, Priyanshu M Sinha, Michael R Horsman, Jens Overgaard.

Observations of previous publications:

- Inconsistency in the application of SBRT + Hyperthermia in both preclinical and clinical studies.

Preclinical studies

- **Different time intervals between SBRT and heat in different studies. Eg 30 mins, 1,2,4 and greater than 4 hours.**
- **Different single studies have used different SBRT Fractions.**

Clinical Studies

- **Different patients received different SBRT fractions in different studies.**
- **Some studies combine hyperthermia and thermal ablation.**
- **Different time intervals between various heat fractions received by patients in the same study.**

WAY FORWARDS

Preclinically apply different fractions of **SBRT** and **hyperthermia temperatures** to see which is the most benefit.

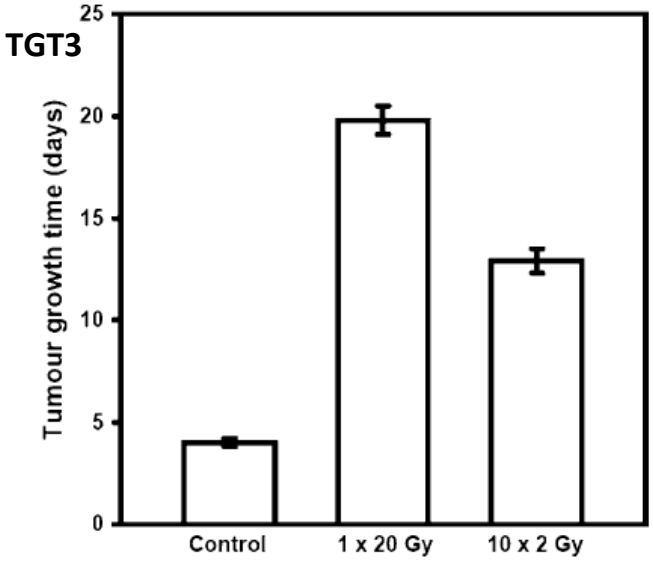
Vary the different temperatures and possible time interval in the process.

HYPERBOOST
Boosting the effect of Radiotherapy

EFFECTS OF STEROITACTIC RADIATION AND HYPERTHERMIA IN PREVIOUS STUDIES IN OUR LAB

❖**C3H mammary carcinoma has responded to both high-dose irradiations and heat in previous studies with CDF1 mice.**

ANIMALS TREATED WITH SINGLE OR FRACTIONATED HIGHER DOSE IRRADIATIONS



All results show means (+-1 SE) from 8-10 mice.

Horsman et al., 2009

ANIMALS TREATED WITH SBRT FRACTIONS COMBINED WITH HYPOXIA MODIFIERS

Treatment groups	Day 0	Day 3	Day 7	3 days after day 7. TCD50 values for clamp top-up dose

HYPERBOOST
Boosting the effect of Radiotherapy

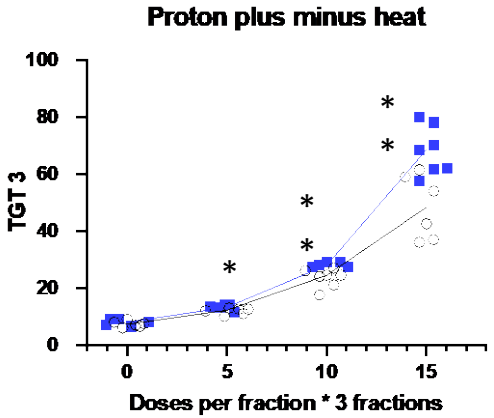
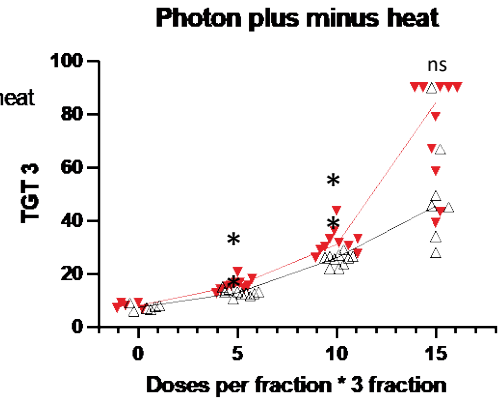
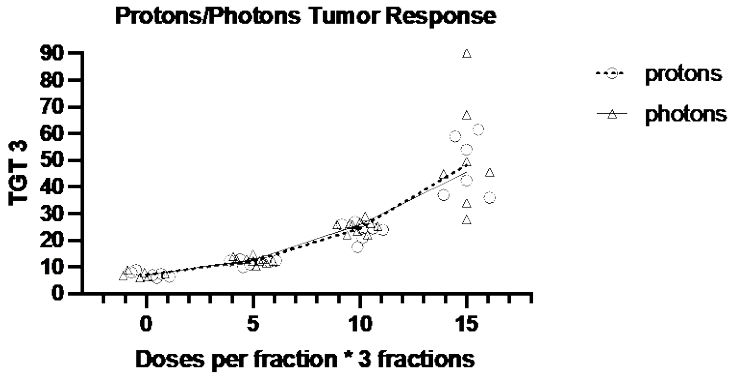
PRELIMINARY RESULTS OF PROTON AND PHOTON SBRT X3 FACTIONS WITH AND WITHOUT HEAT







- **p<0.05; **p<0.01; ns not significant*

- No difference in tumor response between photon and protons SBRT 3F

HYPERBOOST
Boosting the effect of Radiotherapy

INTERIM CONCLUSION

(1) The is optimum beneficial effect of combining hyperthermia with SBRT for both photon and proton at the time interval of 30 mins, heating duration 1 hour.

(2) The cut-off point for the experiment after 90 days (about 3 months) of mice receiving treatment does not show the effects of heat when 3x20Gy ionization irradiation is administered.

(3) SBRT for **Photons and proton** when applied with hyperthermia seems to have the same effects on cancer cells.

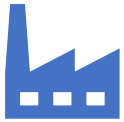
(4) For tumor studies (**tumor delay growth**), the benefits of **SBRT plus heat is seen,** but in normal tissues studies (**data not shown**), hyperthermia + SBRT group shows no statistically significant damage of healthy tissues compared to SBRT group alone.

HYPERBOOST
Boosting the effect of Radiotherapy

FUTURE PROSPECTIVES

Perform toxicity study (acute toxicity). (Ongoing)

Change treatment schedules (vary temperatures and time intervals)



Perform mechanistic studies

ESR4 Azzaya Sengedorj

Elucidate the effects and mechanisms of hyperthermia in combination with radiotherapy on the innate and adaptive immune system in pre-clinical model systems

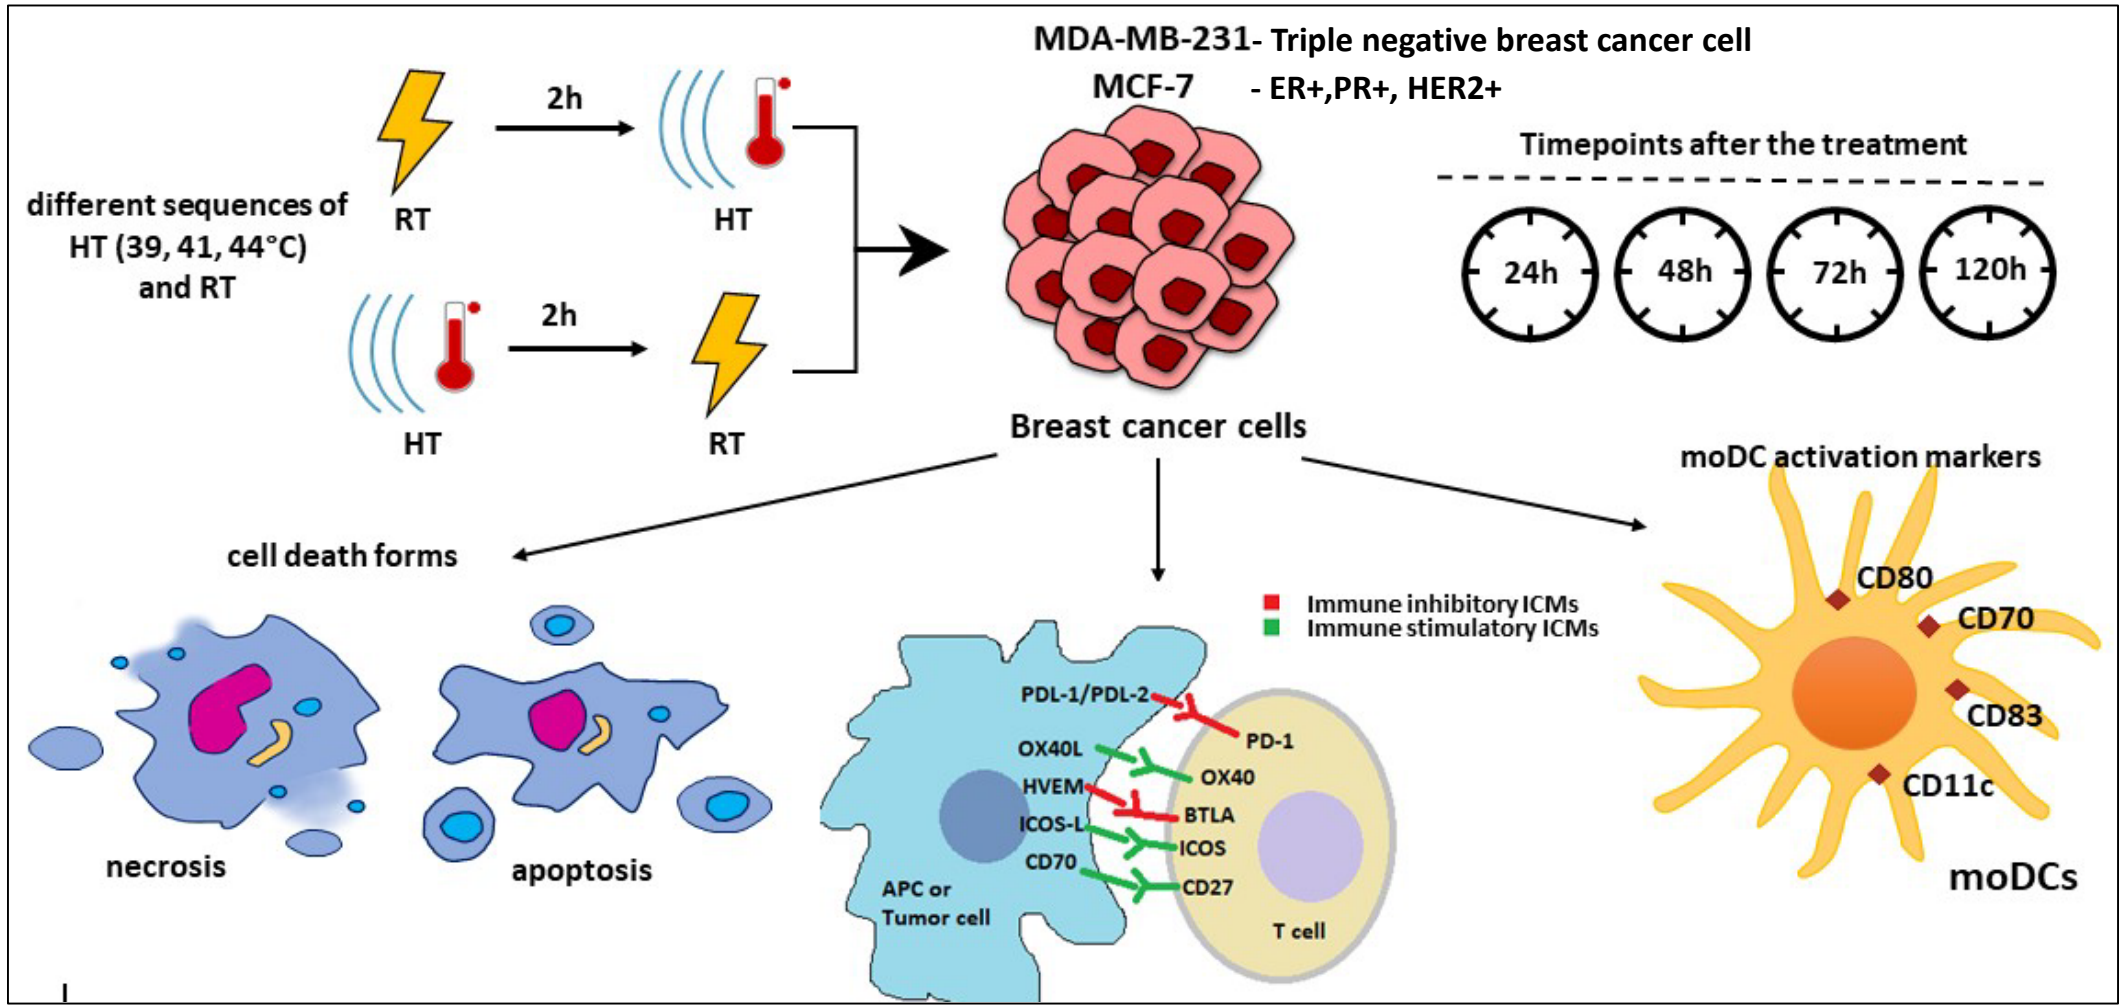
Universitätsklinikum Erlangen (UKER),
Department of Radiation Oncology, Translational Radiobiology,
Universitätsstr. 27, 91054 Erlangen, Germany

Universitätsklinikum Erlangen

Main objective of the project

- To study the effect of hyperthermia treatment in combination with RT on the innate and adaptive immune system
- To investigate if the sequence of HT and RT (either using RT before HT or vice versa) affects differently the immune system
- To determine the effect of HT in combination with RT in induction of anti-tumor immune response by using preclinical and *in vivo* model systems

Effect of hyperthermia and radiation therapy sequence on cell death and the immune phenotype of breast cancer cells

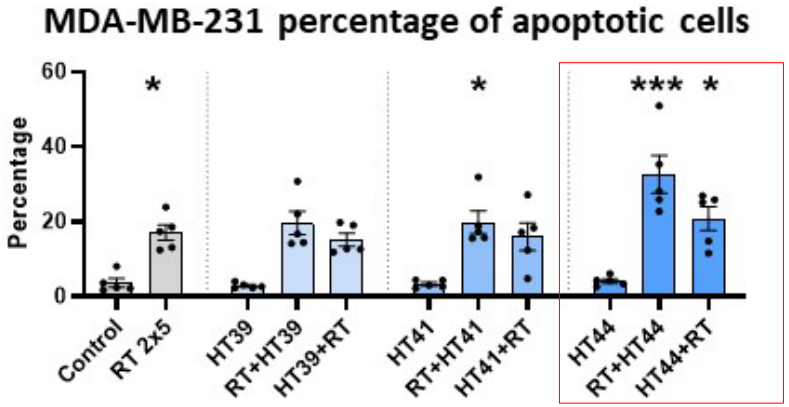


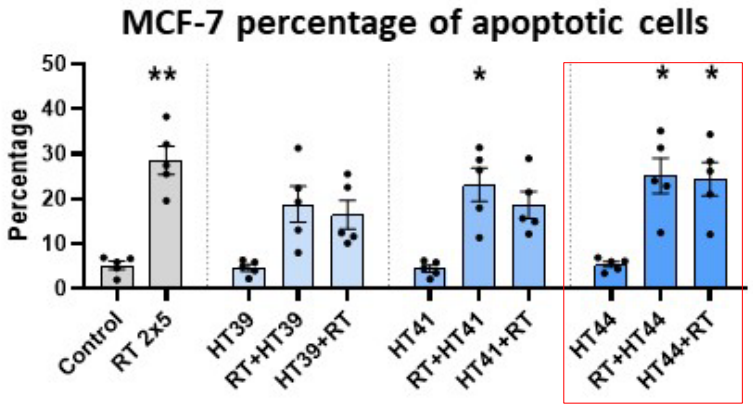
Sengedorj et.al, The Effect of Hyperthermia and Radiotherapy Sequence on Cancer Cell Death and the immune phenotype of Breast Cancer Cells. *Cancers* **2022**, *14*, 2050. https://doi.org/10.3390/cancers14092050

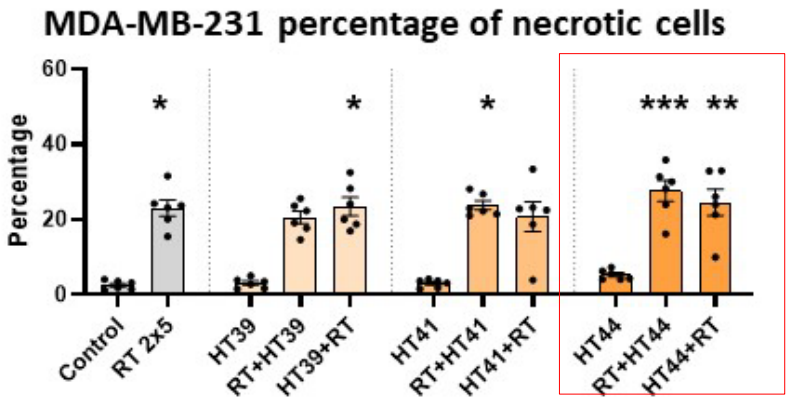
Universitätsklinikum Erlangen

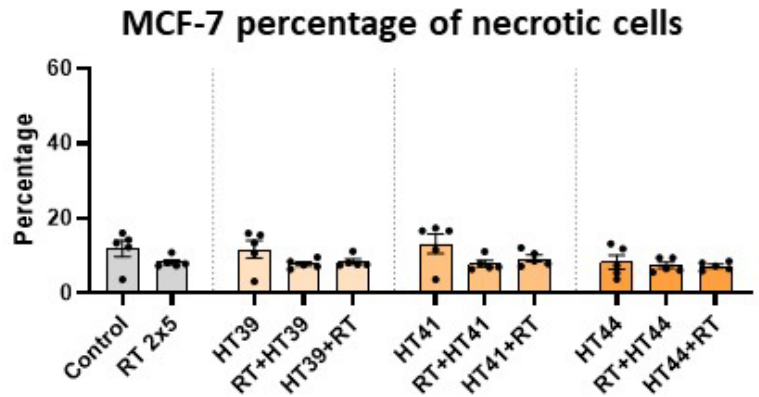
RESULTS

The sequences of HT and RT didn't significantly affect the induction of cancer cell death in MCF-7 and MDA-MB-231 cells









HT in combination with RT significantly induced both apoptosis and necrosis in MDA-MB-231 cells, and apoptosis in MCF-7 cancer cells

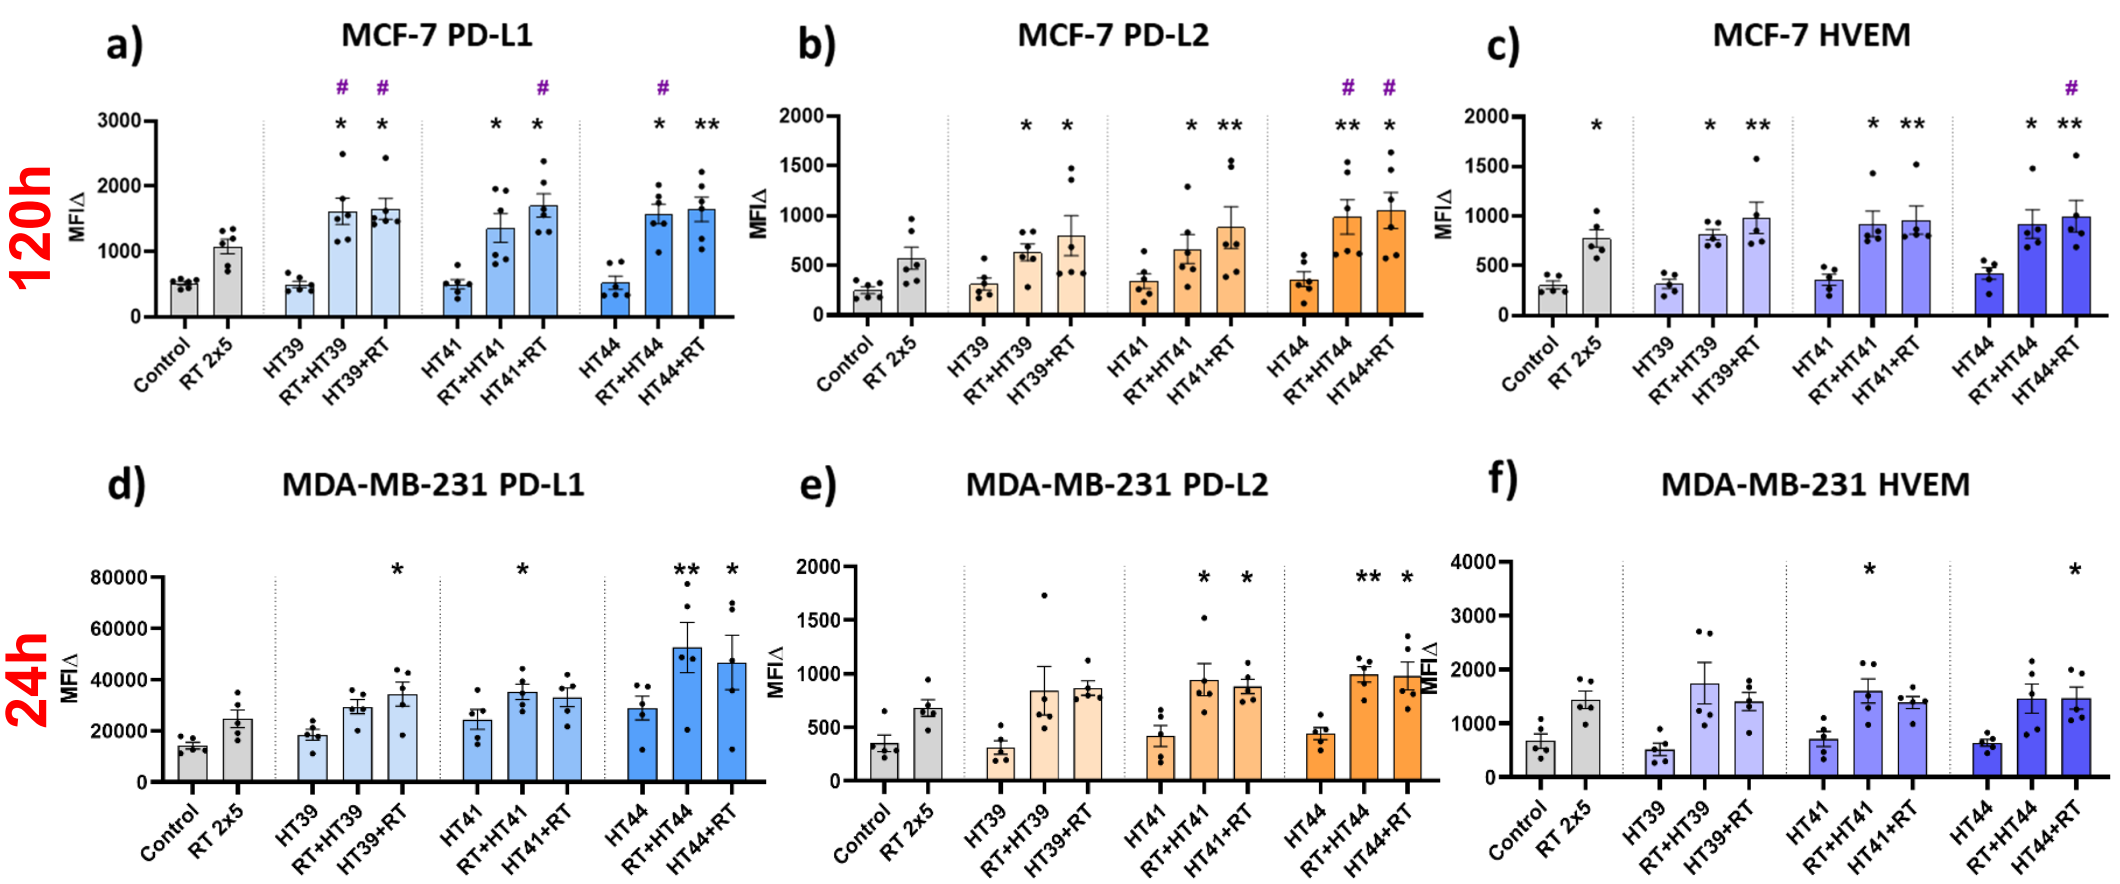
Figure 3: **Cell death of breast cancer cells 120h after the respective treatments**. Mean ± SD are presented from at least five independent experiments. Statistical significance was calculated by using a Kruskall-Wallis test with Dunn's correction * ($p<0.1$), **($p<0.01$), *** ($p<0.001$).

Sengedorj et.al, The Effect of Hyperthermia and Radiotherapy Sequence on Cancer Cell Death and the immune phenotype of Breast Cancer Cells. *Cancers* **2022**, *14*, 2050. https://doi.org/10.3390/cancers14092050

RESULTS:

HT in combination with RT upregulates the expression of inhibitory immune checkpoint molecules in breast cancer cells

Expression of Immune checkpoint molecules in different timepoints



HT boosts the RT's immunosuppressing effect, thus using ICI additional to the RT combined with HT is better

Due to the specific dynamic of ICMs, starting the immunotherapy based on the kinetic of IC molecule expression might be beneficial

Figure 5: **The expression of inhibitory immune checkpoint molecules (PD-L1, PD-L2, HVEM) on MCF-7 (a-c) and particularly PD-L2 on MDA-MB-231 (e) breast cancer cells at 24h and 120h after the treatments.** Mean ± SD are presented from at least five independent experiments. Statistical significance is calculated by using Kruskall-Wallis test with Dunn's correction * (p<0.1), **(p<0.01), *** (p<0.001). RT alone was compared with combinational treatments (HT+RT and RT+HT) by Mann Whitney U test, # (p<0.1).

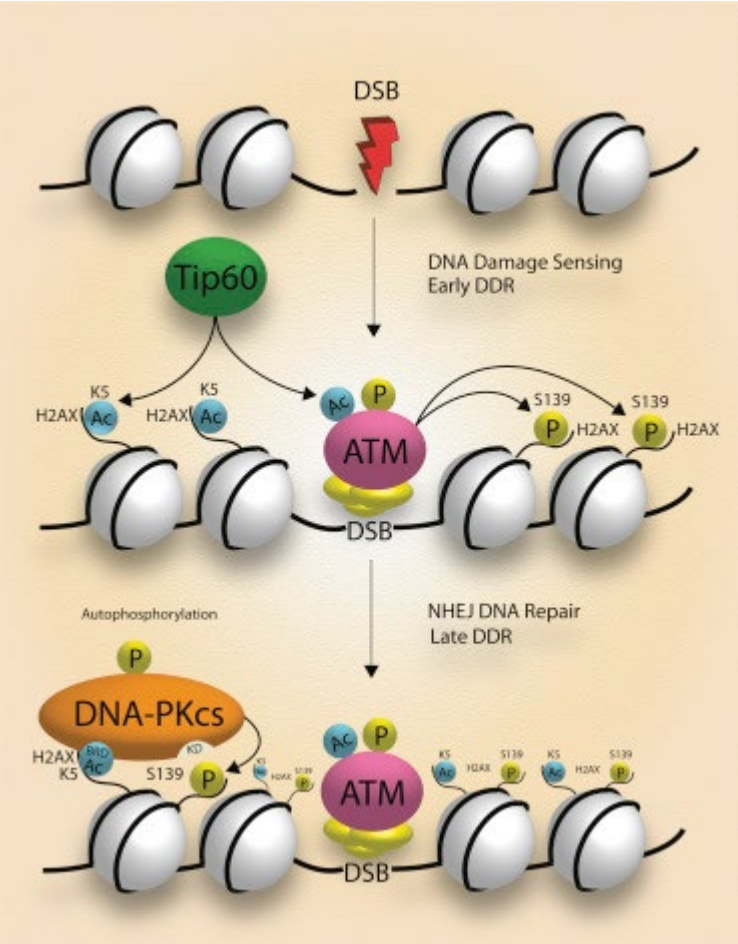
OBJECTIVES

How does the combination of HT and RT affect the DNA damage of cancer cells?

- Analyze yH2AX formation after our treatment setting
- Detection of micronuclei after the treatments
- Analyze the changes of immune related genes after HT
- Analysis of ICM expression on tumor cells after HT and RT
- Investigate whether micronuclei formation is affected by HT and RT, and if this formation activates cGAS STING pathway and changes ICM expression on tumor cells

yH2AX is a sensor for DNA double strand breaks



- yH2AX- phosphorylation of the Ser-139 residue of the histone variant H2AX
- Senses double strand break on DNA, and further activates the DNA damage repair mechanism
- Immunofluorescense detection of yH2AX is very sensitive and reliable method to detect DSBs (double strand break)

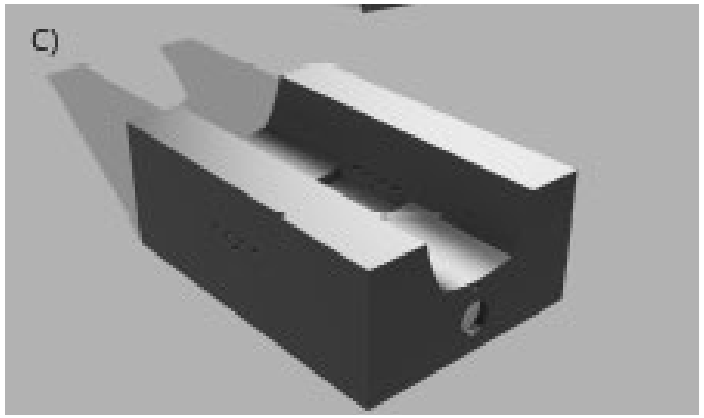
NEW MICROWAVE APPLICATOR EXPERIMENT

M.Sc. Benjamin Kahlert
Strahlenklinik,Universitätsklinikum Erlangen



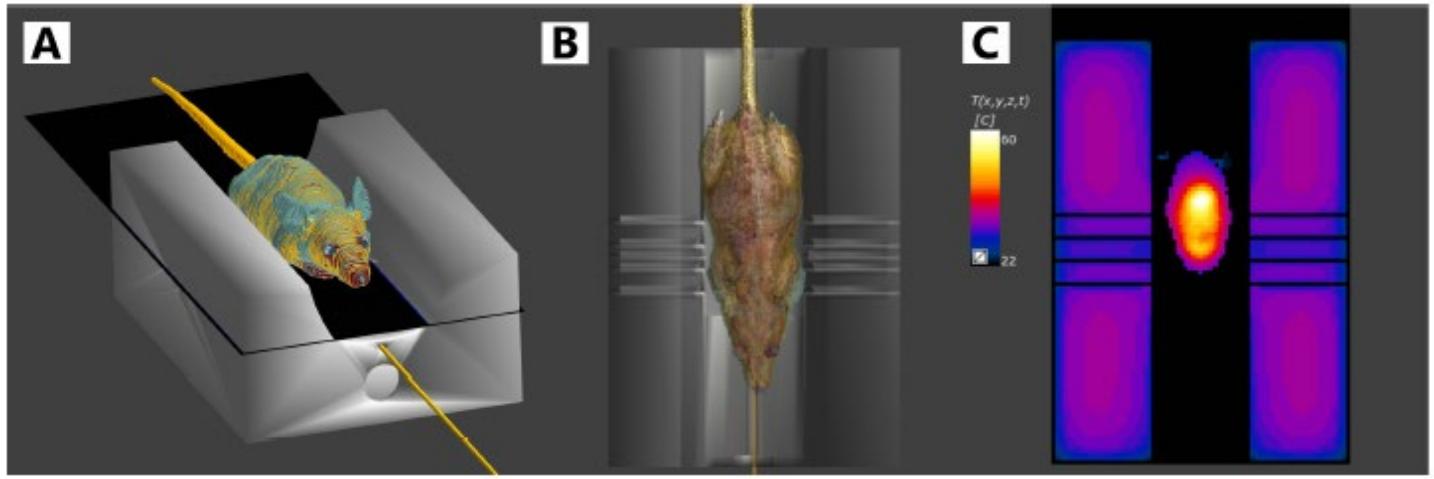


Figure 44: A) Side view of mouse in applicator and shown temperature plane. B) Top down view used in C) for temperature profile.

Conclusion and future plans

- HT combined with RT, in particular when HT is applied before RT it significantly induces more DNA damage, and furthermore impairs DNA damage repair system of cancer cells
- HT combined with RT also affects the expression of immune checkpoint (IC) molecules, this can be explained by different pathways but most significant pathway is cGAS-STING pathway
- The role of Micronuclei formation and how it is activates cGAS-STING pathway and furthermore immune response is under investigation
- Microwave heating applicator for mice is under development, further *in vivo* experiments will be done with this heating method
- Experiments in breast cancer organoids are being considered in the near future

Training experience within the network

- Collaborative work with Dr. Sennewald Medizintechnik, to optimize a microwave hyperthermia applicator for **in vivo** experiments
- Collaborative work with **ESR1**, Amsterdam University Medical Centers, to define immune parameters after HT and RT treatments and DNA damage induced by HT and RT
- Occasional meetings within hyperboost community

HYPERBOOST

Boosting the effect of Radiotherapy

The use of survival dose-rate dependencies as theoretical discrimination criteria for in-silico dynamic radiobiological models

ESR: Sergio Mingo Barba
PI: Prof. Dr. Stephan Scheidegger

This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 955625. This website reflects only the author's view and the European Commission is not responsible for any use that may be made of the information it contains

Objectives of the project

WP4 goal: Develop a biological Treatment Planning System (TPS) for RT+HT.

ESR5 contribution: Radiobiological models

Model-based data analysis of tumor response to RT+HT (focus on cellular level, but with MHR model that can be linked to the cell population model → tissue / tumour ecosystem dynamics!)

↓

Identification of key processes observed by preclinical and clinical results as well as in silico studies on different scales (**cellular**, tissue, immune system).

↓

Evaluating and establish a mathematical model which can be integrated into a RT+HT biological Treatment Planning System .

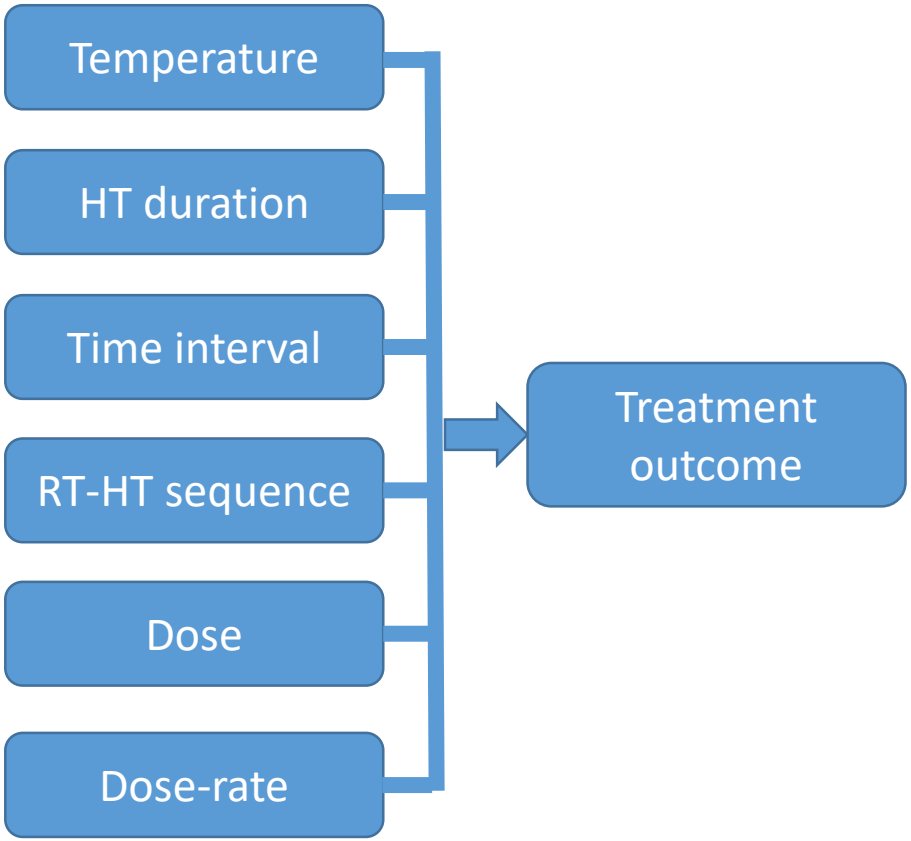
HYPERBOOST
Boosting the effect of Radiotherapy

Aim of radiobiological models

	Predictive (survival)	Systems Biology Approach
Aim	Only interested in the end-point	Understand biological effects evolution
Dynamical models	No	Yes
Study scenarios out of the calibration range	No	Yes (NOT prediction, but helps to understand!)
Complexity	Simplified	More complex
Computation speed	Fast	Slow

HYPERBOOST
Boosting the effect of Radiotherapy

Why do we need in-silico models?



Treatment optimization (schedule, dose, etc.)

↓

Understand the effect of each variable

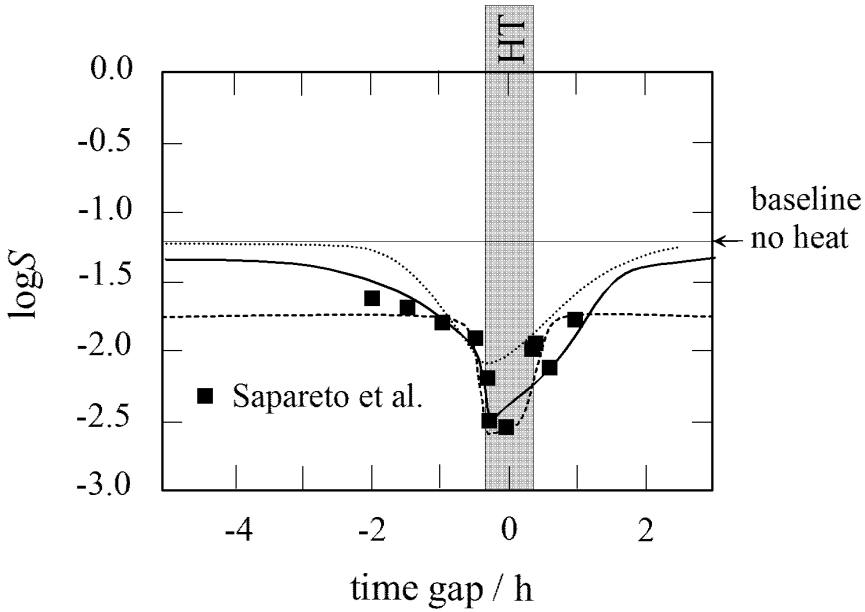
↓

Radiobiological models

HYPERBOOST
Boosting the effect of Radiotherapy

Why do we need dynamical models?

- For synergistic effects of HT and RT, repair speed is essential.
- Reported repair speeds in literature show a wide spread.
- Problem: Repair is a result of complex competing processes, dependent on a large number of parameters including dose, dose rate.
- We have to **understand** repair speeds (as a dynamical process), not only to know them!



Fit of experimental data (redrawn) from (Sapareto et Al., 1978). Chinese hamster cells were irradiated with 5 Gy prior (negative time gap) or after heat (positive time gap). Heat (HT) is applied during 40 min (±20 min of point 0 on the time gap axis). Temperature T during heating was 42.5°C.

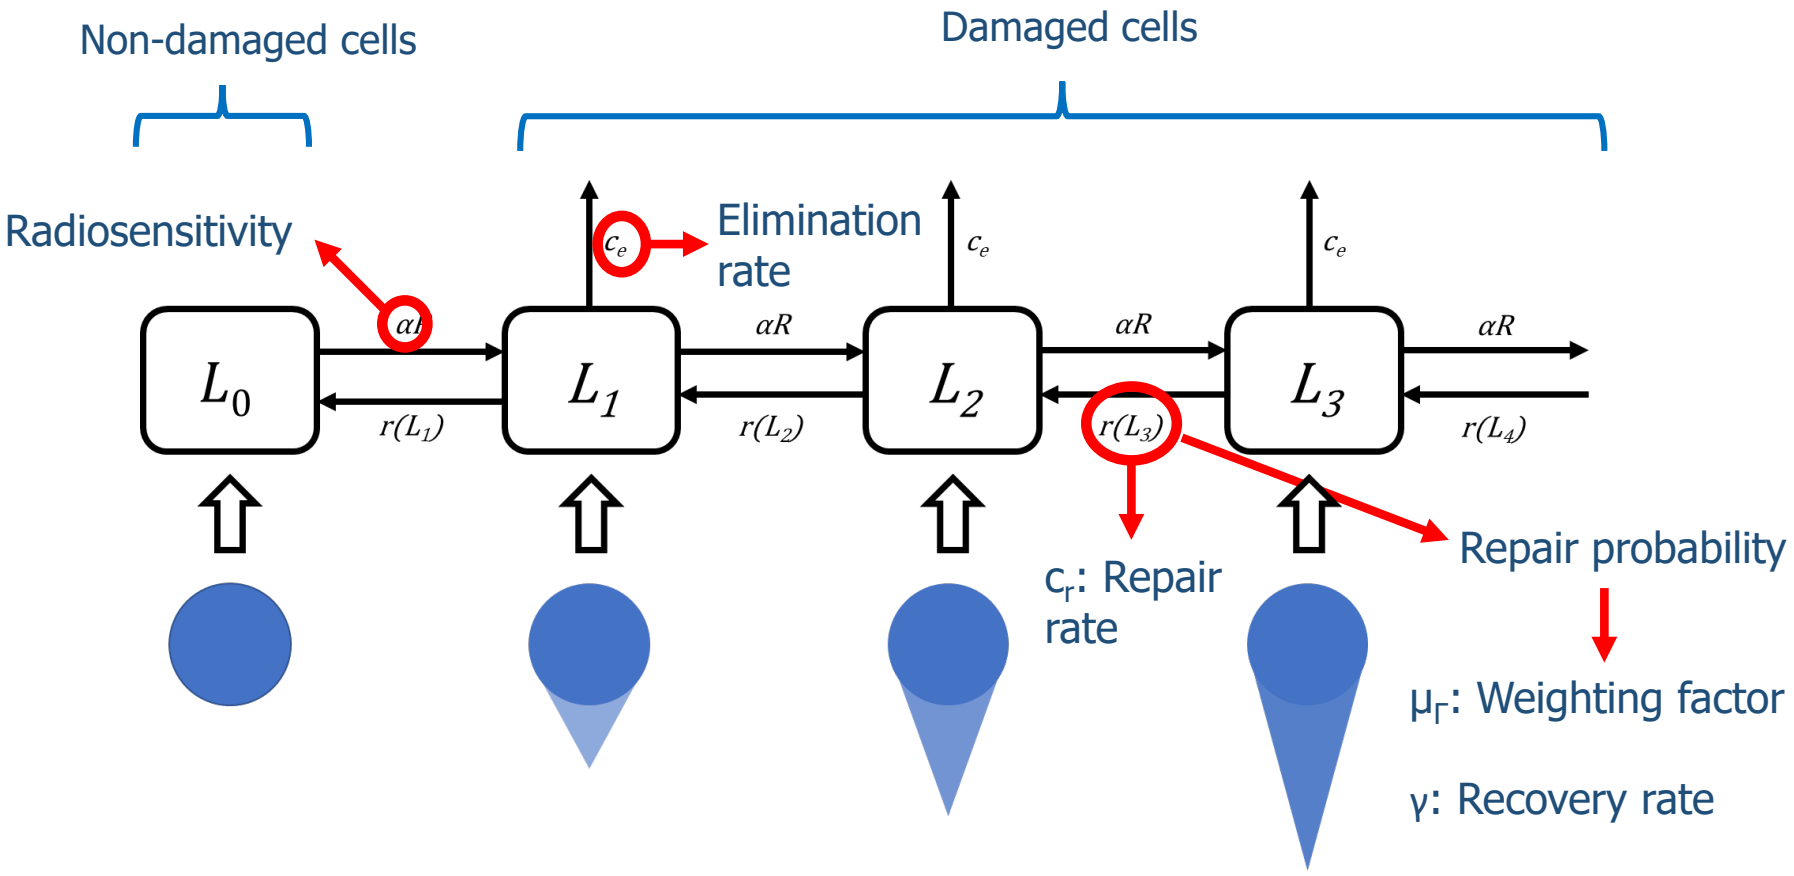
Boosting the effect of Radiotherapy

S. A. Sapareto, L. Hopwood, and W. Dewey, "Combined effects of x-irradiation and hyperthermia on CHO cells for various temperatures and orders of application," Radiation Research, vol. 44, pp. 221–233, 1978.

The Multi-Hit Repair (MHR) model



- Chain structure needed to explain LQ survival and dose-rate effects and to compare with comet data.

HYPERBOOST
Boosting the effect of Radiotherapy

Scheidegger, S.; Fuchs, H.U.; Zaugg, K.; Bodis, S.; Füchslin, R.M. Using state variables to model the response of tumour cells to radiation and heat: A novel multi-hit-repair approach. Comput. Math. Methods Med. 2013, 2013, doi:10.1155/2013/587543.

Experimental data and model calibration

- Canine osteosarcoma Abrams cells (6 Gy/min).

Survival: Clonogenic assay

- Doses: 3 and 6 Gy.

DNA-damage: Time-resolved comet assay

- Dose: 6 Gy.
- Times: 15 mins- 6 hours.

- Combined objective function:

$$\varepsilon_{combined} = \varepsilon_{clonogenic} + \xi \varepsilon_{comet}$$

- Approximate Bayesian Computational (ABC) method → **Probability distributions** of parameters are obtained!

Conclusions

- A combination of different experiments *in-vitro* and *in-silico* is probably the best approach to study cell repair dynamics.
- 99% of the parameters sets are filtered by the dose-rate theoretical discriminators.
- Dose rate discriminators and combined fitting of different assays are a powerful tool to avoid model falsification!
- MHR model calibration is improved (but not yet completed, also due to model adaption)
- More dynamical information is required for a proper model calibration (**in progress**):
  - Analysis of survival dose-rate experimental data.
  - Inclusion of HT survival data.
  - DNA damage time-resolved assays, e.g. comet assay or γH2AX.
- Variants of the MHR model (e.g., the implementation of clustered hits) should be considered.

Boosting the effect of Radiotherapy

Tumor Control Probability (TCP) calculation to theoretically study the impact of different treatment conditions

This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 955625. This website reflects only the author's view and the European Commission is not responsible for any use that may be made of the information it contains

Introduction

- **Aim:** To obtain biological information from patient data treated with HT.

- **Problems:**
  - Small number of patients.
  - Heterogeneous treatment conditions (temperatures, thermal/radiation dose, tumor type, etc).
  - Patient complexity.
  - «Logistically» challenging to get the data.

- **Proposed strategy:** Use existing biological models to calculate the expected TCP under diverse conditions → What can we expect to find from the patient data?

(van Leeuwen et al., 2017) model: Radiosensitisation

- Modified LQ model used **to fit** clonogenic data heated during 1 h with different temperatures and time-gaps.

$$\alpha(T, t_{int}) = \alpha_{37} \cdot exp\left[\frac{T-37}{41-37} \cdot ln\left(\frac{\alpha_{41}}{\alpha_{37}}\right) \cdot exp(-\mu \cdot |t_{int}|)\right]$$

$$\beta(T, t_{int}) = \beta_{37} \cdot exp\left[\frac{T-37}{41-37} \cdot ln\left(\frac{\beta_{41}}{\beta_{37}}\right) \cdot exp(-\mu \cdot |t_{int}|)\right]$$

where $\alpha_{37} = \alpha(37,0)$, $\alpha_{41} = \alpha(41,0)$, $\beta_{37} = \beta(37,0)$, $\beta_{41} = \beta(41,0)$, μ (h^{-1}) is the rate at which the radiosensitising effect of hyperthermia disappears, t_{int} (h) is the time interval between radiotherapy and hyperthermia and D (Gy) is the total radiation dose.

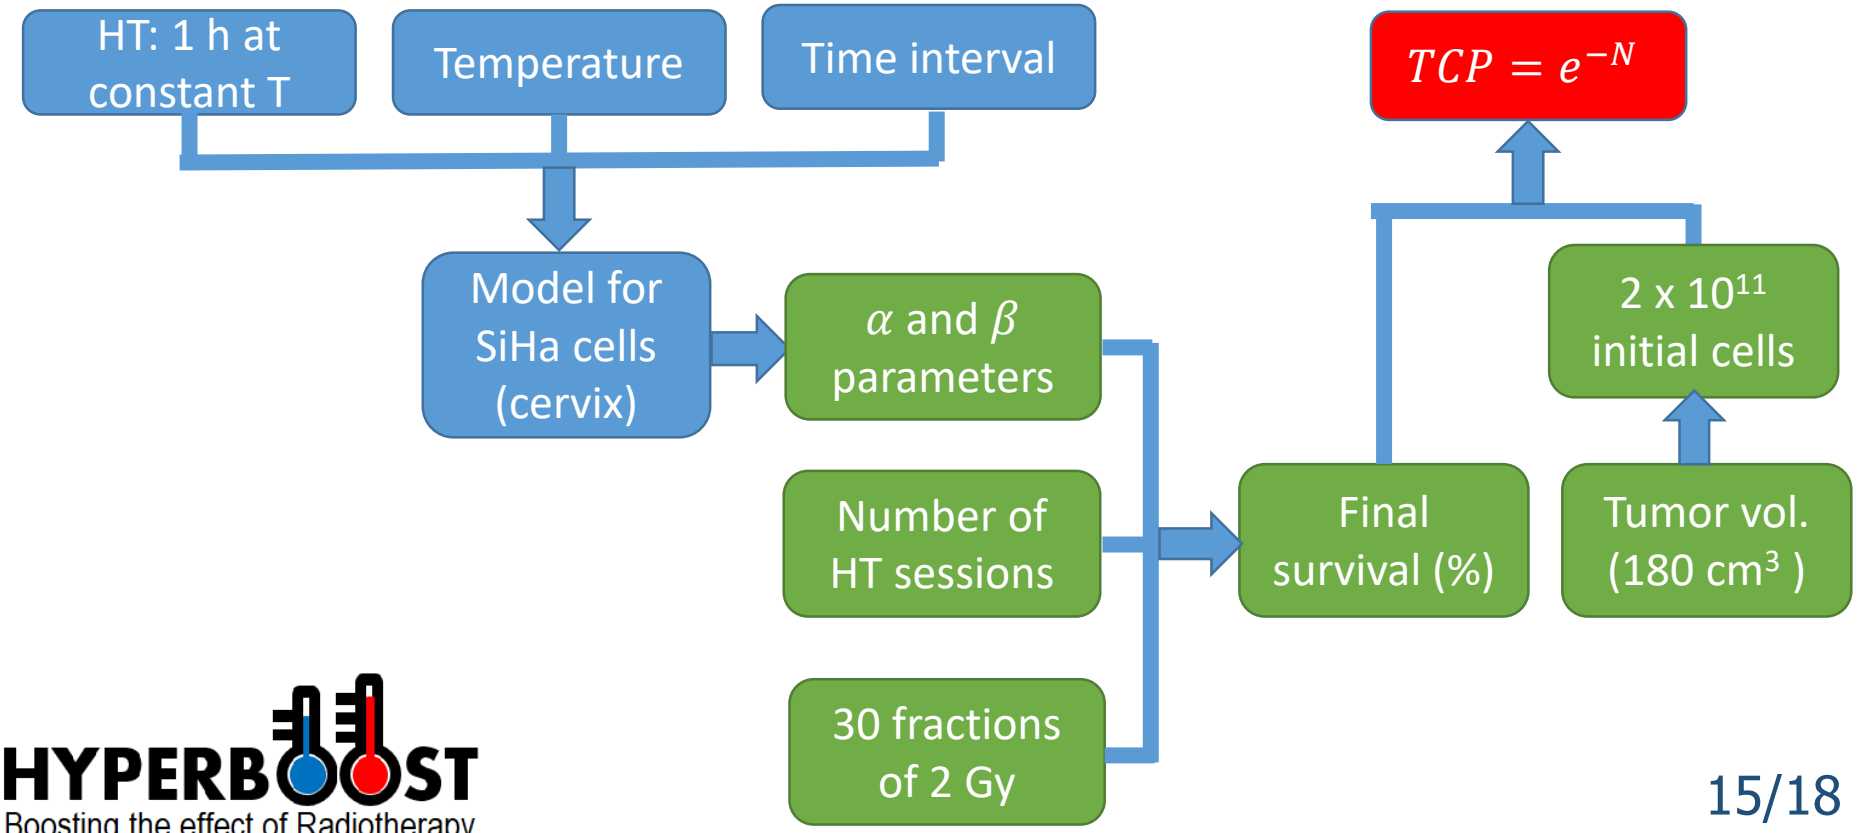
van Leeuwen, C.M.; Oei, A.L.; ten Cate, R.; Franken, N.A.P.; Bel, A.; Stalpers, L.J.A.; Crezee, J.; Kok, H.P. Measurement and analysis of the impact of time-interval, temperature and radiation dose on tumour cell survival and its application in thermoradiotherapy plan evaluation. Int. J. Hyperth. 2017, 34, 30–38, doi:10.1080/02656736.2017.1320812.

Simulated treatment conditions

- Thermal characteristics margins based on patient data.

Number of HT sessions	HT achieved temperatures	Time-gap between HT and RT
3-6	39-43 °C	8-60 min

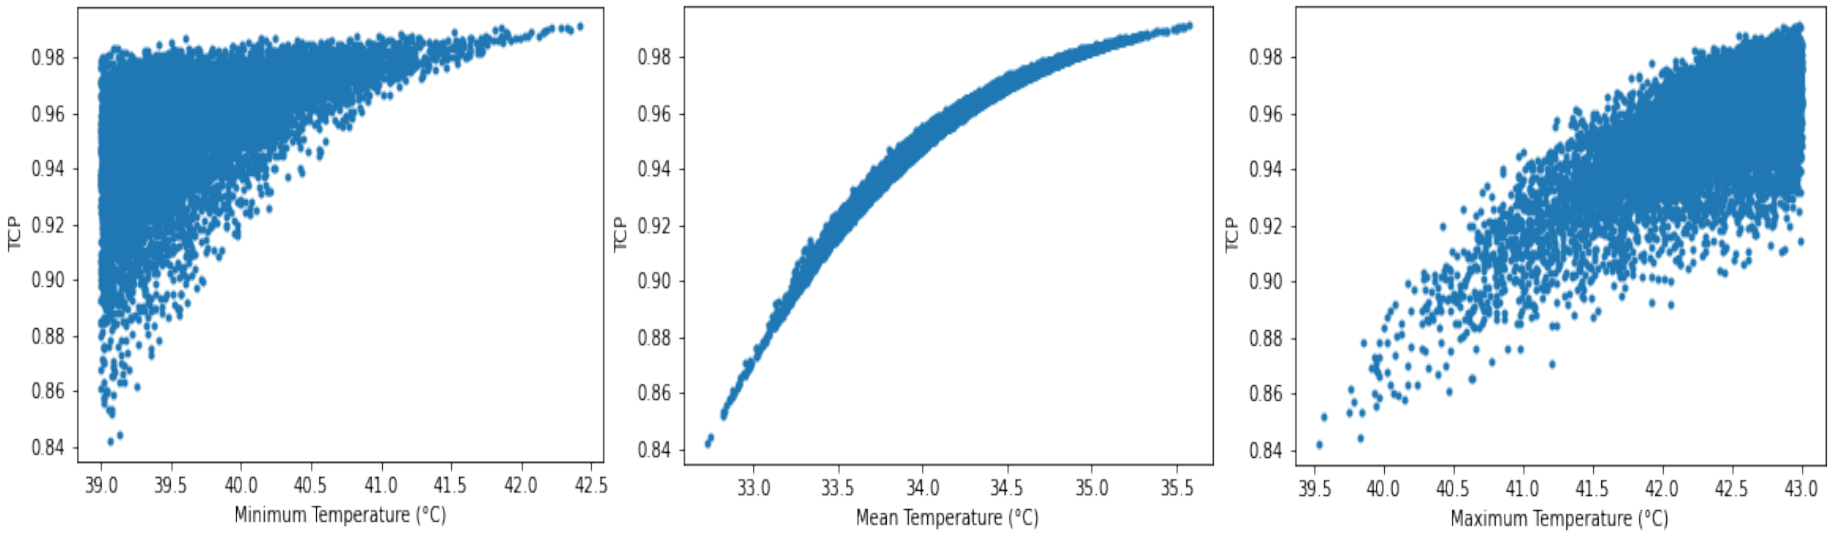
Margins established for the thermal treatments based on the available patient data at KSA.



HYPERBOOST
Boosting the effect of Radiotherapy

Results: Temperature dependence

5 HT sessions with 10 mins of time-gap and random temperature for each sessions



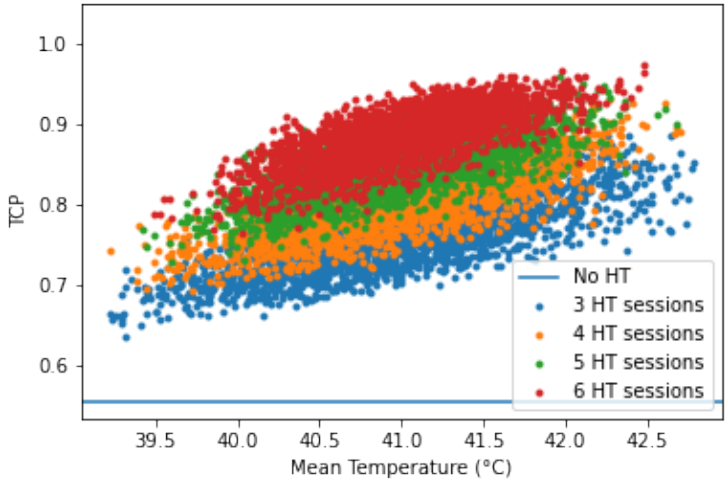
Obtained TCP values for 10^4 dummy patients after 5 HT sessions with 10 minutes of time-gap achieving a temperature randomly selected for each HT session. The dependence on the mean achieved temperature (left) and the mean time-gap (right) are plotted when direct cell killing is considered (low row) or not (up row). For these simulations, a decay constant of $\mu=1.0\ h^{-1}$ is considered.

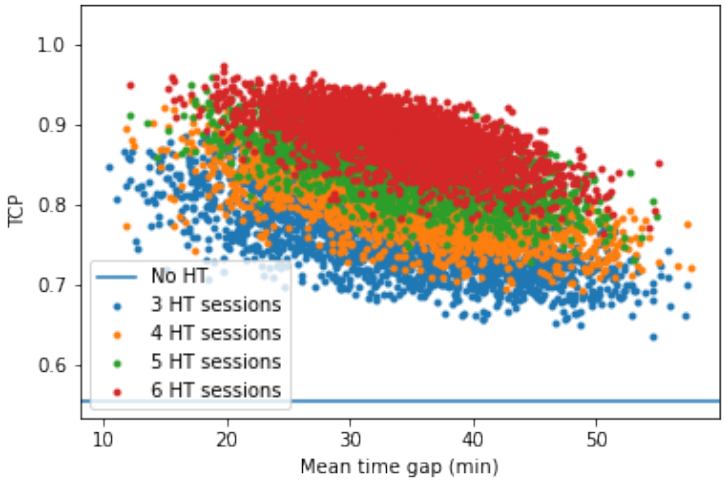
Overall treatment seems more important than single HT session.

HYPERBOOST
Boosting the effect of Radiotherapy

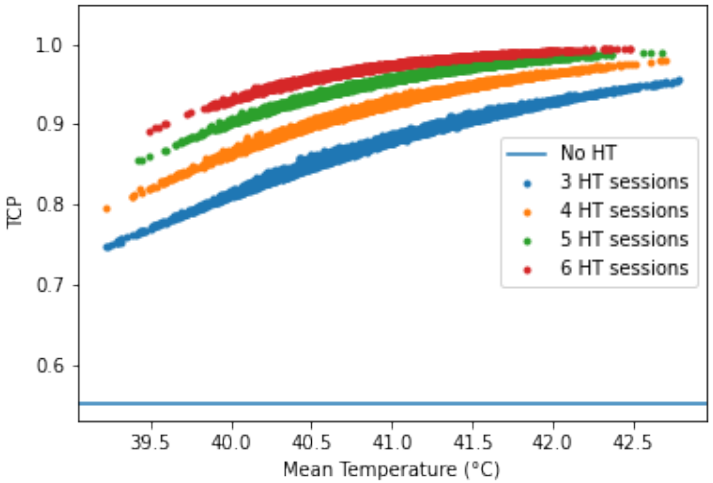
Results: Random conditions

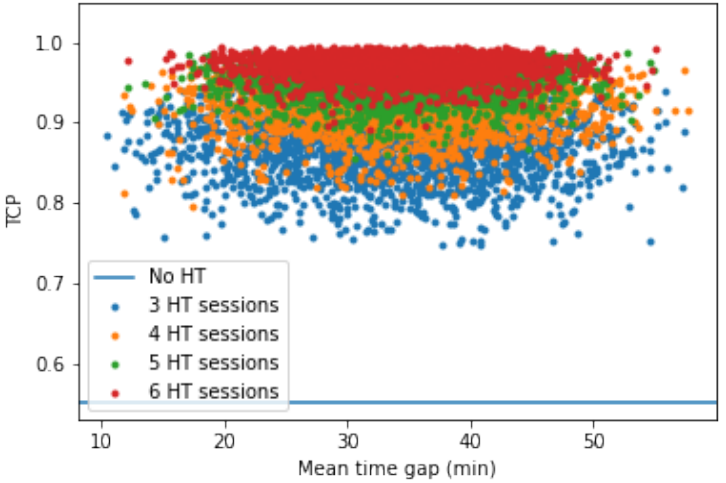
t_{int} important:
μ=1.0 h^{-1}





t_{int} NOT important:
μ=0.027 h^{-1}





Obtained TCP values for 10^4 dummy patients with number of HT sessions, time-gaps and achieved temperature randomly selected for each HT session. The dependence on the mean achieved temperature (left) and the mean time-gap (right) are plotted when a decay constant of μ=1.0 h^{-1} (up row) or μ=0.027 h^{-1} (low row) is considered.

HYPERBOOST
Boosting the effect of Radiotherapy

Conclusions

- Cellular radiobiological models can be used to theoretically have an idea of the clinical results which might be expected.

- The treatment outcome (from the cell radiosensitisation point of view) is more related to the overall treatment than to a single HT session.

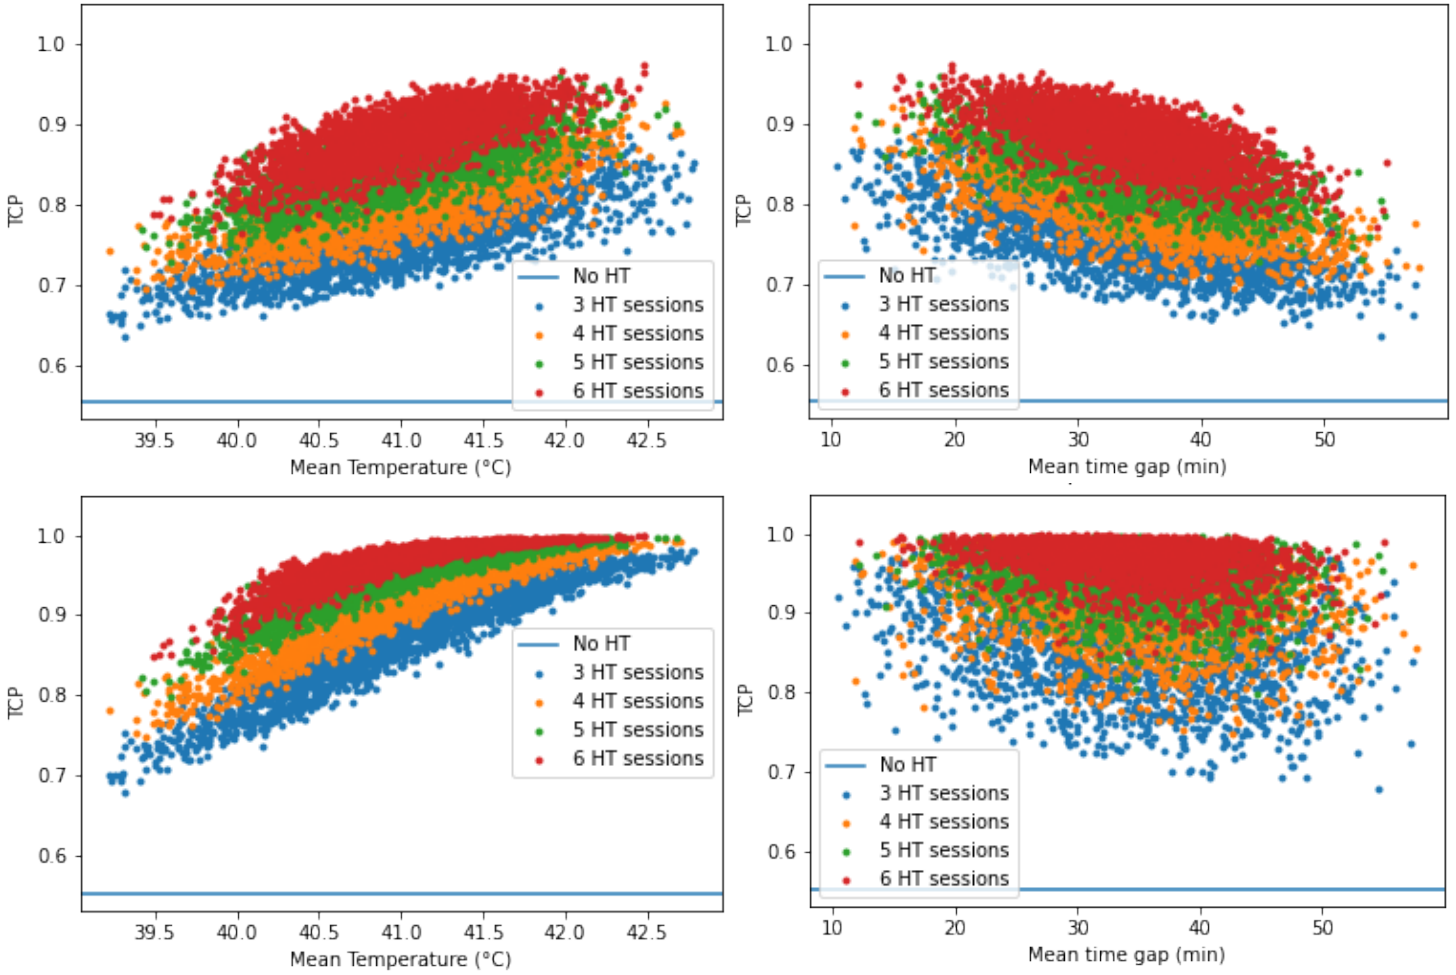
- The time-gap importance could be deduced from the temperature dependence.

HYPERBOOST
Boosting the effect of Radiotherapy

Results: Random conditions (μ=1.0 h^{-1})

No direct cell HT killing

Direct cell HT killing



Obtained TCP values for 10^4 dummy patients with number of HT sessions, time-gaps and achieved temperature randomly selected for each HT session. The dependence on the mean achieved temperature (left) and the mean time-gap (right) are plotted when direct cell killing is considered (low row) or not (up row). For these simulations, a decay constant of μ=1.0 h^{-1} is considered.

HYPERBOOST

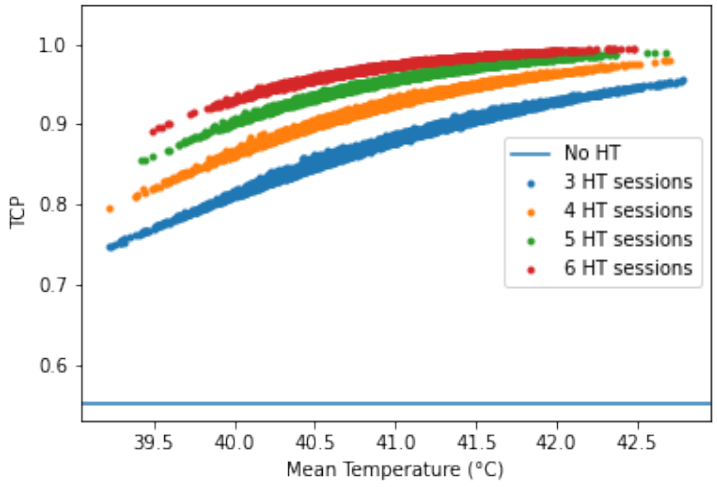
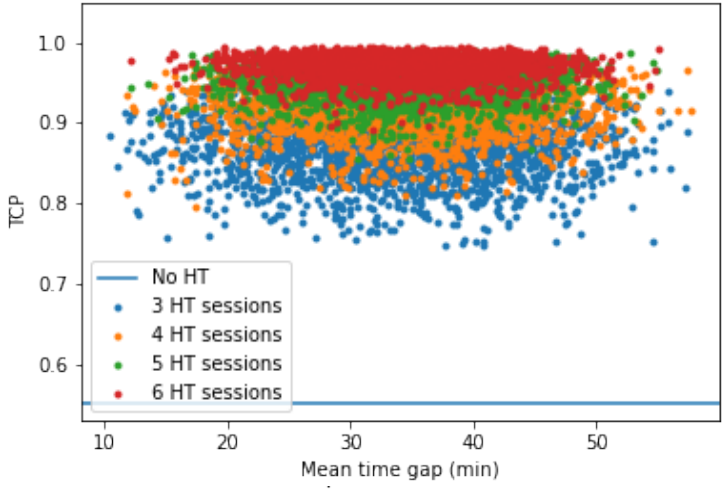
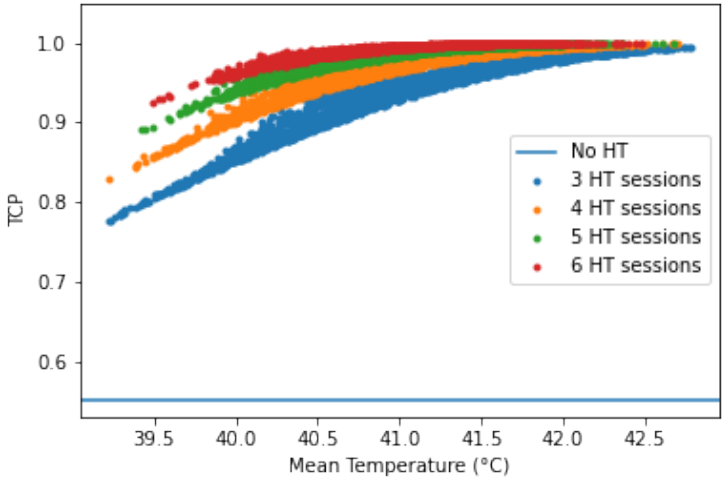
Results: Random conditions (μ=0.027 h^{-1})

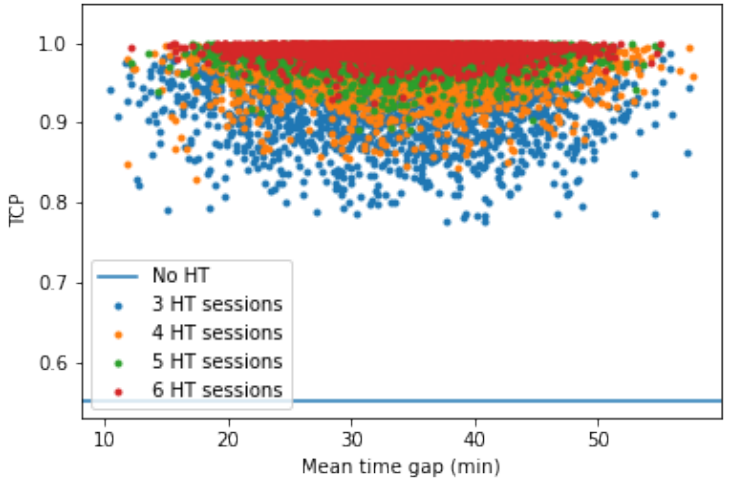
No direct cell HT killing





Direct cell HT killing





Obtained TCP values for 10^4 dummy patients with number of HT sessions, time-gaps and achieved temperature randomly selected for each HT session. The dependence on the mean achieved temperature (left) and the mean time-gap (right) are plotted when direct cell killing is considered (low row) or not (up row). For these simulations, a decay constant of μ=0.027 h^{-1} is considered.

HYPERBOOST
Boosting the effect of Radiotherapy

(van Leeuwen et al., 2017) model: Direct HT killing

- Hyperthermic cytotoxicity survival (SF_{HT}) given by

$$SF_{HT}(T,t) = exp[-k(T) \cdot t]$$

with t (s), the heating time and k the reaction rate as a function of the temperature T (°C), given by

$$k(T) = 2.05 \cdot 10^{10} \cdot (T + 273.15) \cdot exp\left[\frac{\Delta S}{2} - \frac{\Delta H}{2 \cdot (T + 273.15)}\right]$$

where ΔS (cal/°C/mol) is the entropy of inactivation and ΔH (cal/mol) is the inactivation energy of the critical rate-limiting molecules that cause cell lethality.

Model calibration

- Approximate Bayesian Computational (ABC) method:
  - Iterative perturbative method used to minimize an error function.
  - Provides several final parameters sets → The model parameters distributions can be studied.

- Feeding of data for model calibration:
  - **Clonogenic:** Final number of undamaged cells.
  - **Comet:** Comet tail intensity ↔ Model population.

- Combined error function:

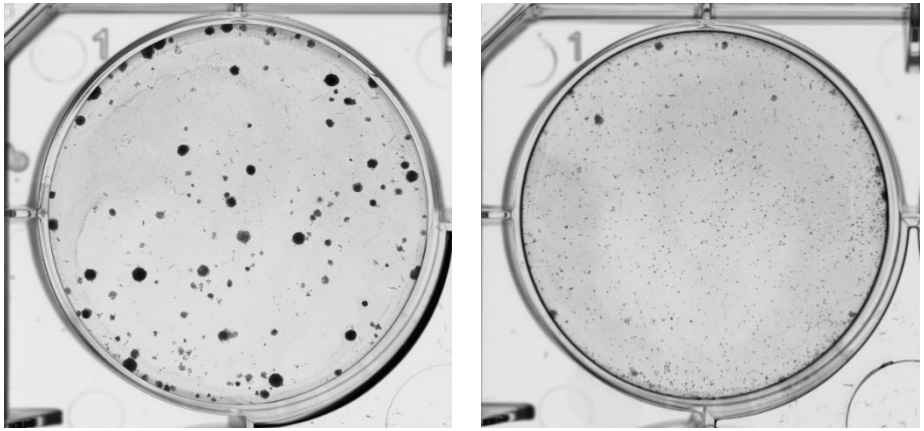
$$\varepsilon_{total} = \varepsilon_{survival} + \xi \cdot \varepsilon_{comet}$$

where ξ is a weighting factor.

HYPERBOOST
Boosting the effect of Radiotherapy

Experimental data: Clonogenic assay

- Canine osteosarcoma Abrams cells.
- Irradiation dose-rate: 6 Gy/min.
- Doses: 3 and 6 Gy.



Example of colonies formation in the clonogenic assay for SiHa cancer cells after.

$$Survival = \frac{Final\ \#\ colonies}{Initial\ \#\ cells}$$

HYPERBOOST
Boosting the effect of Radiotherapy

Procedure

1. Make dilutions to obtain the desired initial number of cells.
2. Plate the cells and leave then incubation during 4 h.
3. Treat the cells.
4. Leave the cells incubating and growing during two weeks.
5. Throw the medium and treat the cells with crystal violet to make the colonies visible.
6. Count the number of colonies (≥50 cells).

HYPERBOOST
Boosting the effect of Radiotherapy

Experimental data: Comet assay

- Canine osteosarcoma Abrams cells.
- Irradiation dose-rate: 6 Gy/min.
- Dose: 6 Gy.
- Times: 15 mins-1 hour.

The Multi-Hit Repair (MHR) model

HYPERBOOST
Boosting the effect of Radiotherapy

Main ideas

- Use a chain of cell populations characterize by the number of radiation induced damages (hits).
- Lethality → Removal from the mitotic cycle.
- Use state variables for a simplistic description of the impact of heat and radiation upon repair proteins.

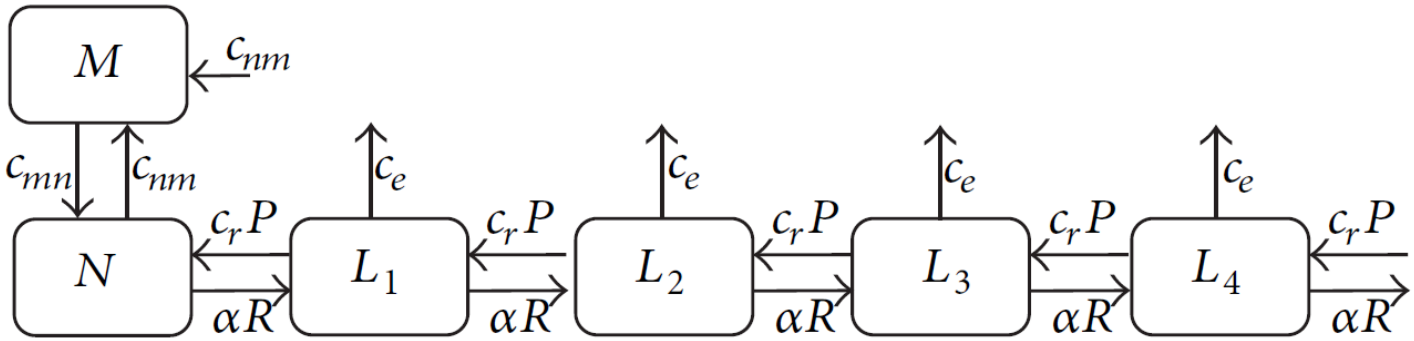

Illustration of the population model.

HYPERBOOST
Boosting the effect of Radiotherapy

Radiation Induced Protein-Related Damage (Γ-LQ model)

- Dose equivalent Γ → Transient dose (Repair proteins)

$$\frac{d\Gamma}{dt} = R - f(\Gamma)$$

R=Dose rate

f(Γ)=Kinetics of protein-related damage repair function

- In this paper: $f(\Gamma) = \gamma\Gamma$

$$\lim_{t\to\infty}\left[\int_{-\infty}^{t} f(\Gamma(\tau))d\tau\right] = \lim_{t\to\infty}[D(t)] = D_{tot}$$

D_{tot}=Total cumulative dose

HYPERBOOST
Boosting the effect of Radiotherapy

Heat-Induced Protein-Related Damage

$$\frac{d\Upsilon}{dt} = -k_1\Upsilon + k_2\Lambda$$

$$\frac{d\Lambda}{dt} = k_1\Upsilon - k_2\Lambda$$

Υ/ Λ = Proportion of functional/non-functional repair proteins

k_1/k_2 = Thermal degradation/repair of proteins constants

$$k_1 = a \cdot 10^{-3} \cdot e^{\frac{E_a}{R(273{,}15+37℃)} - \frac{E_a}{R(273{,}15+T(℃))}}$$

E_a = Activation energy

HYPERBOOST
Boosting the effect of Radiotherapy

Calculation of Repair Probability

- Monotonically decrease with Λ and Γ:

$$\left[\frac{\partial P}{\partial \Lambda}\right]_{\Gamma=const.} = -\mu_\Lambda P \quad \rightarrow P(\Lambda) = e^{-\mu_\Lambda \Lambda}$$

$$\left[\frac{\partial P}{\partial \Gamma}\right]_{\Lambda=const.} = -\mu_\Gamma P \quad \rightarrow P(\Gamma) = e^{-\mu_\Gamma \Gamma}$$

- Statistically independent:

$$P = P(\Lambda, \Gamma) = P(\Lambda) \cdot P(\Gamma) = e^{-\left(\mu_\Gamma \Gamma + \mu_\Lambda \Lambda\right)}$$

HYPERBOOST
Boosting the effect of Radiotherapy

Multi-Hit Repair and Population Model

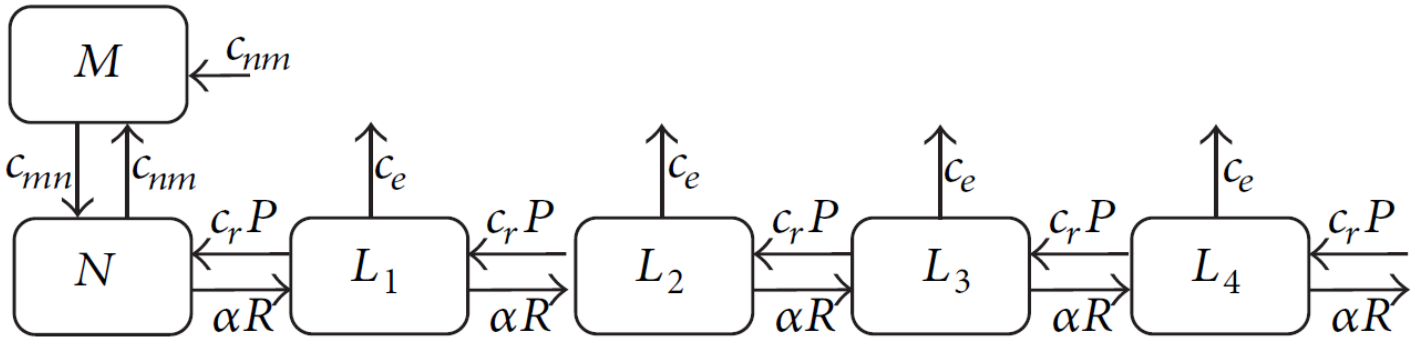

Illustration of the population model.

$$\frac{dN}{dt} = -\alpha RN + r(L_1) = -\alpha RN + c_r e^{-\left(\mu_\Gamma \Gamma + \mu_\Lambda \Lambda\right) L_1}$$

$$\frac{dL_k}{dt} = \alpha R L_{k-1} - \alpha R L_k - r(L_k) + r(L_{k+1})$$

- Apoptotic cell death $\rightarrow -c_e L_k$
- HT cytotoxicity $\rightarrow -a_k \cdot 10^{10}\left(273{,}15 + T(°\mathrm{C})\right) \cdot e^{\frac{\Delta S}{R} - \frac{\Delta H}{R\left(273{,}15 + T(°\mathrm{C})\right)} L_k}$

Robust optimization and evaluation of radiotherapy combined with hyperthermia based on equivalent enhanced radiation dose

Timoteo D. Herrera, Jakob Ödén, Andrea Lorenzo, Hans Crezee, H. Petra Kok

Hyperboost Meeting 2023 - Erlangen

This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 955625

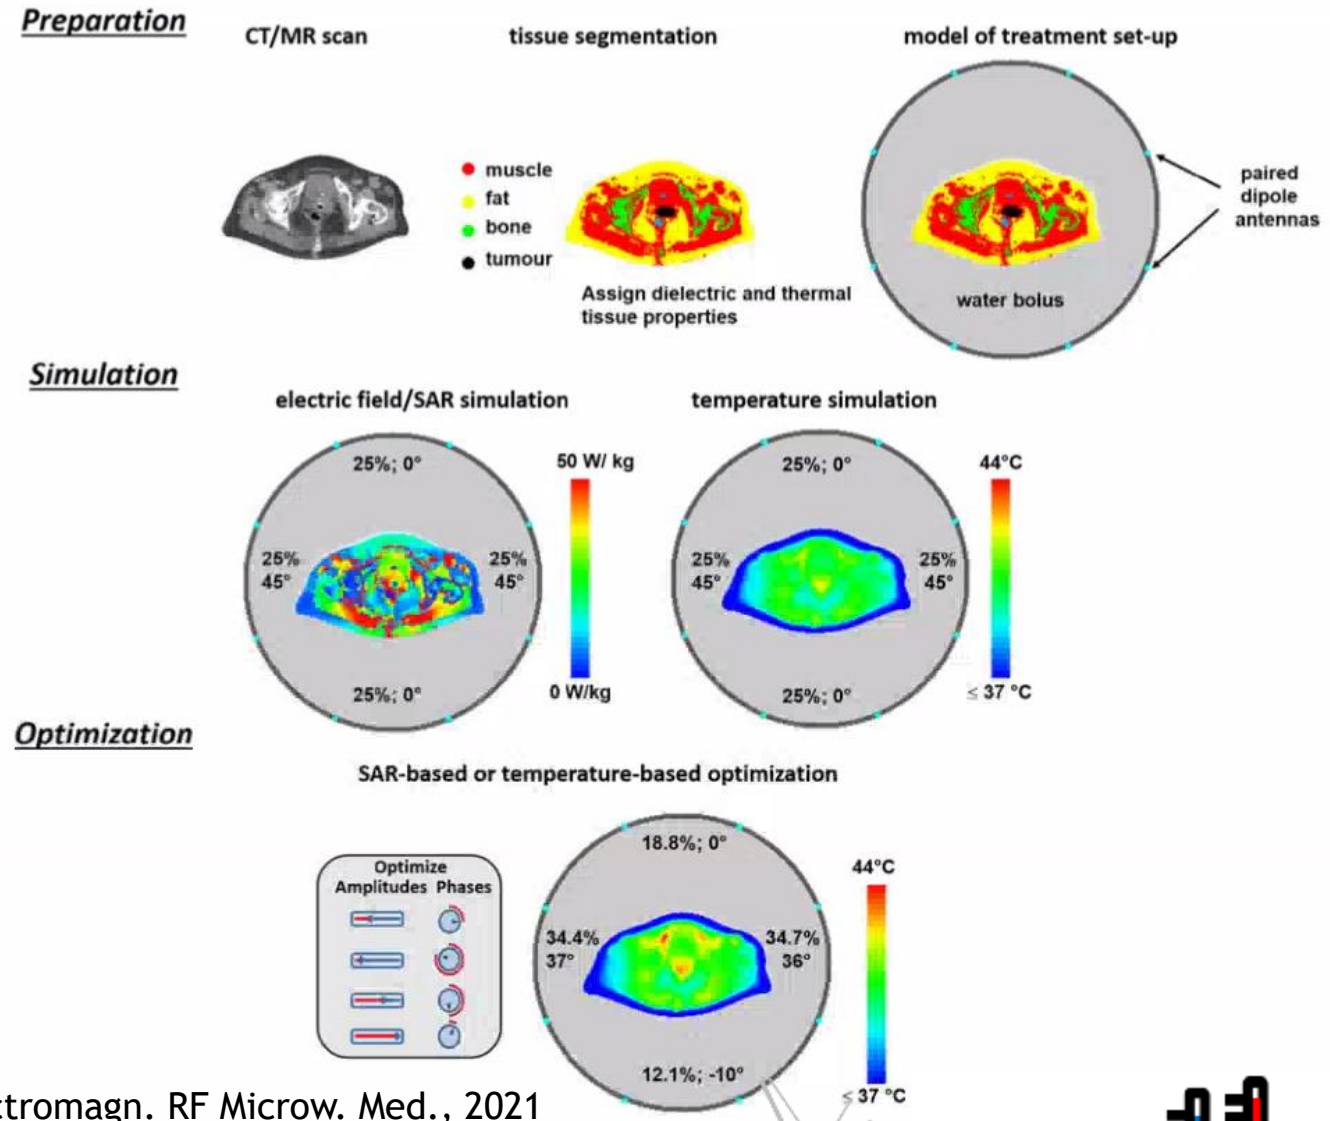
HYPERBOOST
Boosting the effect of Radiotherapy

Outline

- Introduction: Hyperthermia in combination with radiotherapy
- Motivation – Hyperboost Project and RaySearch secondment
- Implementation – Robust optimization and evaluation
- Some results
- Summary and future work

Hyperthermia Treatment Planning

- Limited clinical application
  - Device configuration
  - Heating ability evaluation
  - Assistance on-line treatment guidance
- Ongoing research to improve reliability and increase applicability
  - Patient-specific dielectric properties
  - Perfusion and oxygenation modelling
  - Biological modelling of response.



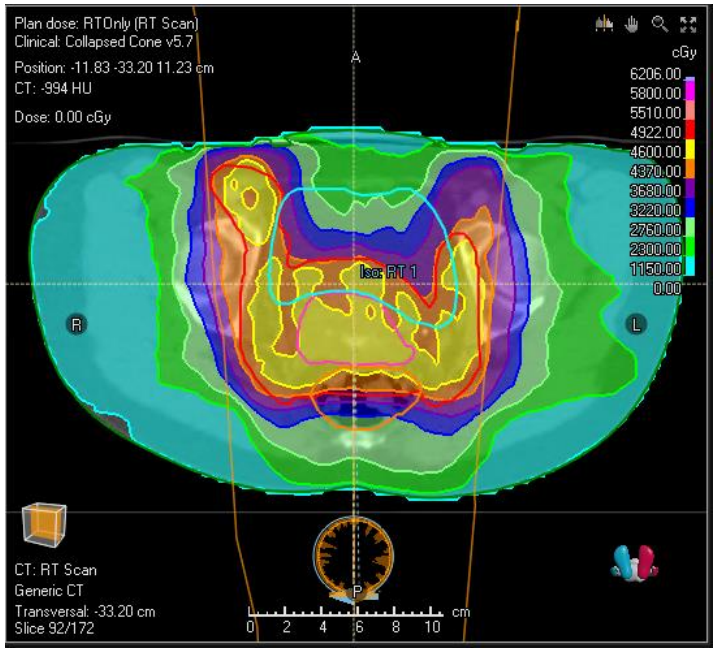
Kok and Crezee, IEEE J. Electromagn. RF Microw. Med., 2021

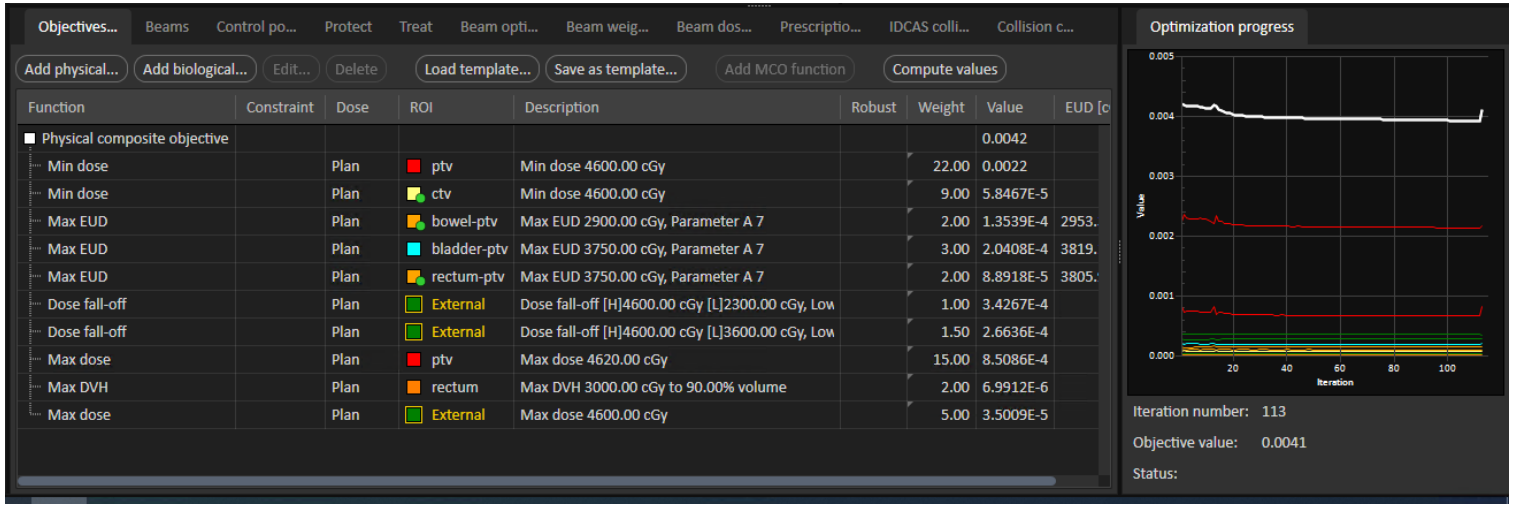
RaySearch Laboratories

HYPERBOOST
Boosting the effect of Radiotherapy

Radiotherapy Treatment Planning

- Standardized prescription for indication, based on results of clinical trials:
  - Dose coverage for treatment volumes: GTV, CTV, PTV
  - Dose limits for organs at risk
- Modulated techniques, optimization of objective functions related to the prescription.
  - Dose distribution is optimized at a voxel level.





RaySearch Laboratories

HYPERBOOST
Boosting the effect of Radiotherapy

Modeling the combined treatment

- Linear Quadratic Model (LQM):
- Survival fraction

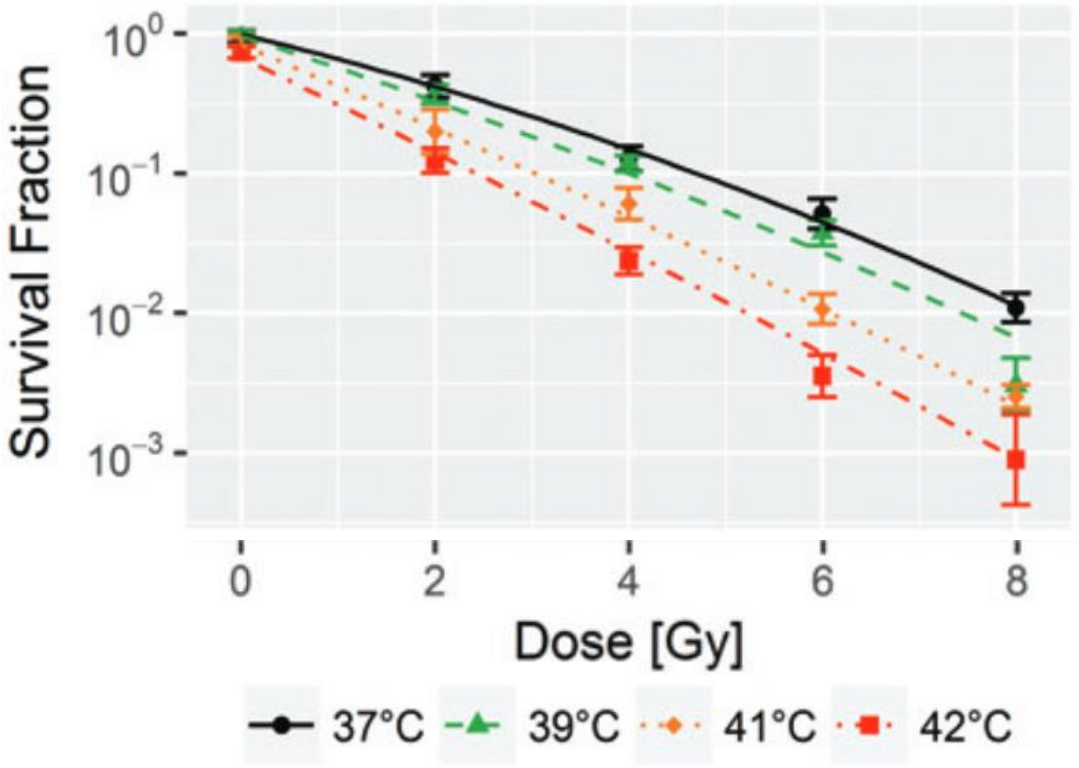
$$SF = e^{-n(\alpha d + \beta d^2)}$$

- α, ß, radiosensitivity parameters
- Comparison of fractionation schemes:

$$EQD_2(d) = \frac{nd(\alpha + \beta d)}{\alpha + 2\beta}$$

With hyperthermia:

- Cell survival assay of RT + HT (no interval between modalities) for a cervical cancer cell line.
- Similar curves for different time intervals of up to 4 h.



Van Leeuwen et al. Int J Hyperth 2018

RaySearch Laboratories

HYPERBOOST
Boosting the effect of Radiotherapy

Equivalent dose for RT + HT

- α_{37}, β_{37} parameters from linear quadratic model at baseline temperature (37°C)
- α_{41}, β_{41} modified LQ-parameters reflecting the synergistic effect at 41°C
- $T_{1/2}$ time decay of the synergistic effect
- $c(T)$ direct thermal cell kill

- $EQD_{RT}(T, t_{int}, D) = \frac{\alpha(T,t_{int})\cdot D+\beta(T,t_{int})\cdot D^2+c(T)}{\alpha_{37}+2\cdot\beta_{37}}$

- $\alpha(T, t_{int}) = \alpha_{37} \cdot exp\left[\frac{T-37}{41-37} \cdot ln\left(\frac{\alpha_{41}}{\alpha_{37}}\right) \cdot exp\left(\frac{-\ln(2)\cdot|t_{int}|}{T_{1/2}}\right)\right]$

Van Leeuwen et al. Int J Hyperth 2018

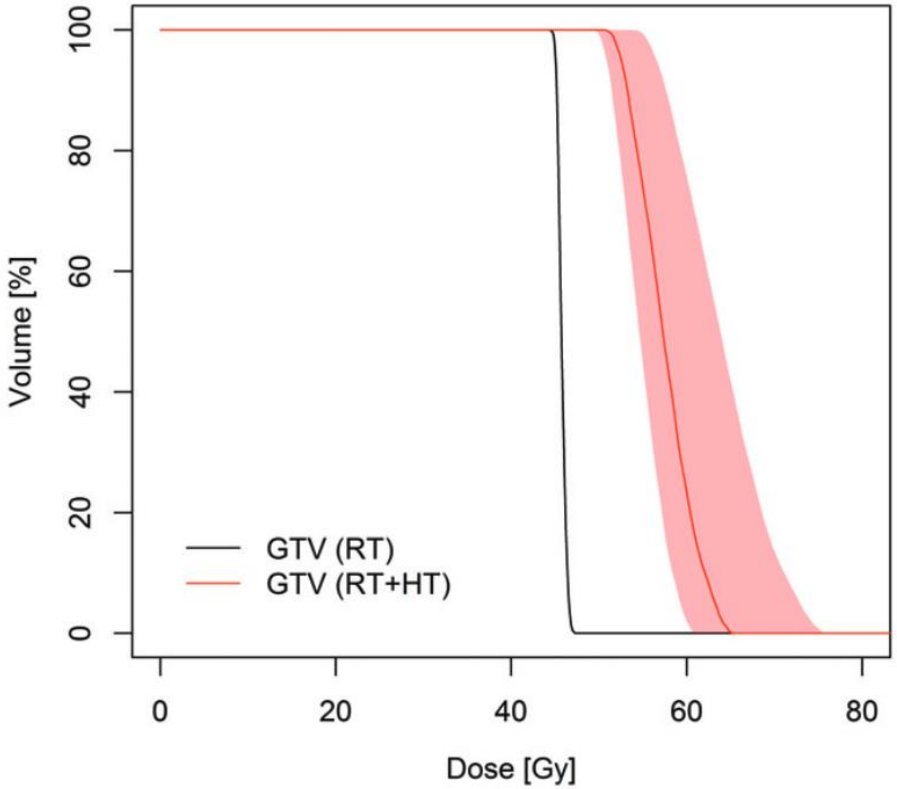
- $\beta(T, t_{int}) = \beta_{37} \cdot exp\left[\frac{T-37}{41-37} \cdot ln\left(\frac{\beta_{41}}{\beta_{37}}\right) \cdot exp\left(\frac{-\ln(2)\cdot|t_{int}|}{T_{1/2}}\right)\right]$

RaySearch Laboratories

HYPERBOOST
Boosting the effect of Radiotherapy

Secondment Project - Motivation

- Optimization (current status):
  - HT is optimized to maximize T90 in the tumor, with normal tissue constraints.
  - RT is optimized independently according to protocol.
  - The resulting EQD_{RT} is heterogeneous, and will depend in the achieved temperature, patient and session dependent.
- Research prototype in RayStation 12A
  - Optimization with temperature as an input using EQD_{RT} model.
  - EQD_{RT} evaluation.

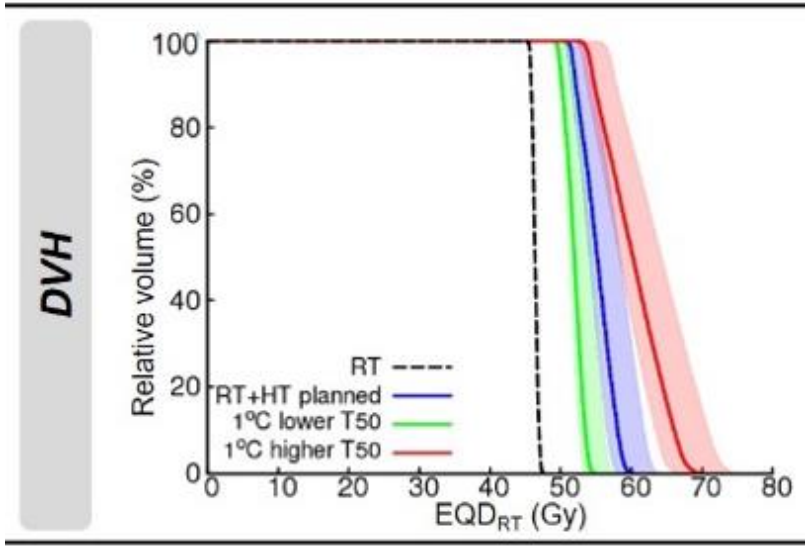


Van Leeuwen et al. Int J Hyperth 2018

Secondment Project - Motivation

- Robustness in deep locoregional hyperthermia:
  - Not many degrees of freedom compared to RT
    - 4 antennas: amplitude and relative phase, total power
  - Steering of amplitude and phase during treatment
    - Focus on the tumor
    - Hot spots/patient complaints (avoid T>45° C)
  - Determinants of the temperature level:
    - Amplitudes and phases
    - Power increase/decrease
    - Changes in perfusion
    - Patient-specific dielectric properties

EQD_{RT} for a cervical cancer patient, effect of scaling of temperature



Kok et al. Int J Radiat Oncol Biol Phys 2022

RaySearch Laboratories

HYPERBOOST
Boosting the effect of Radiotherapy

Secondment Project

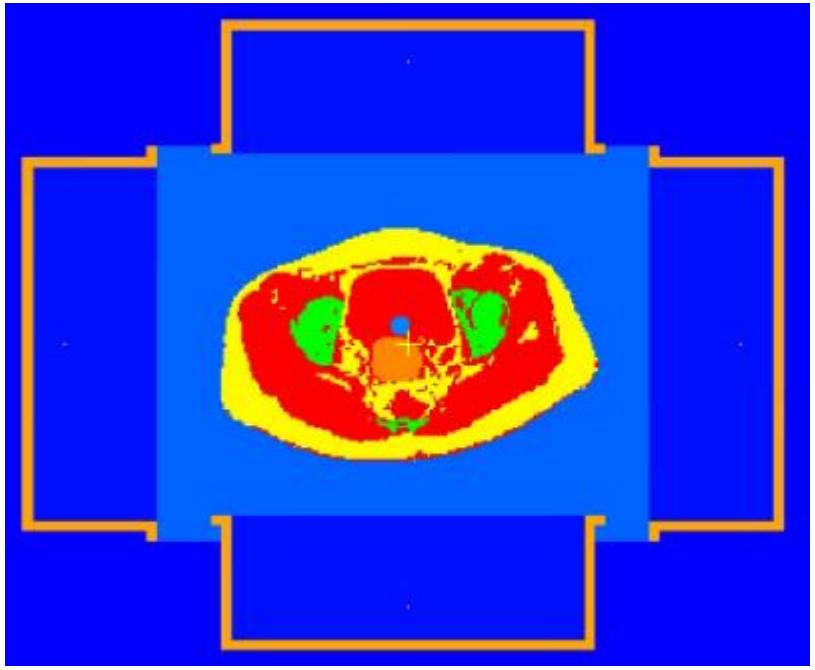
- Objectives:
  - Optimize RT to control level and homogeneity of EQD_{RT}.
  - Robustness evaluation of optimized plans:
    - What happens with level and homogeneity of EQD_{RT} in optimized plans in case of:
      - Phase and amplitude steering
      - Power increase/decrease
      - Increased time interval
  - Robust optimization:
    - Optimized plans for (realistic) alternative scenarios
    - Robustly optimized plan

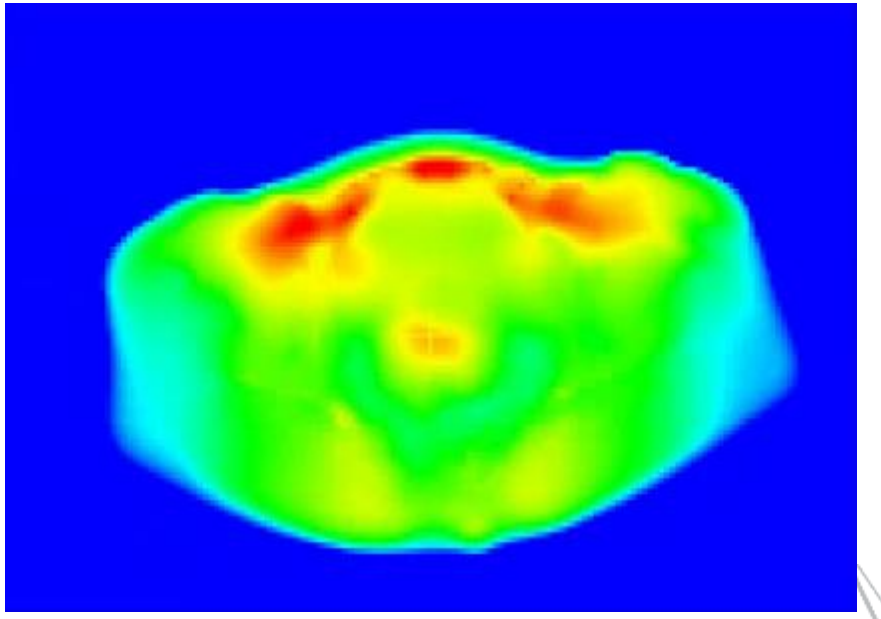
Implementation

Hyperthermia Treatment Planning: research version of Plan2Heat.

- Nominal temperature distribution
  - Maximize T90 in the GTV
  - Hard constraint normal tissue temperature < 45°C
  - Nominal device configuration
    - Total power, amplitudes and phases for each antenna.
- Realistic alternative temperature distributions. Simulate 16 scenarios:
  - Phase-amplitude steering.
  - Power increase/decrease.
  - Change in time interval.

Patient model: segmented tissue types, water bolus and antennas





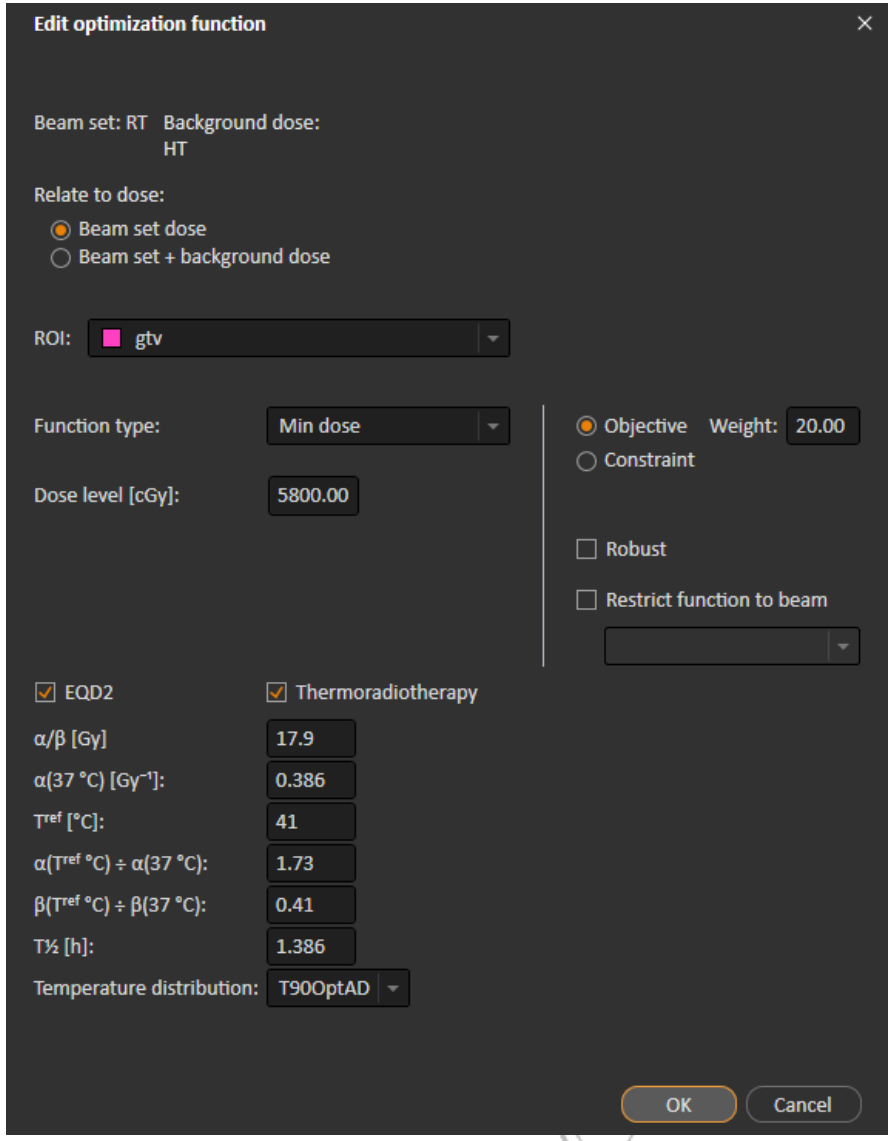
Temperature distribution

RaySearch Laboratories

HYPERBOOST
Boosting the effect of Radiotherapy

Implementation

- Optimization:
  - Optimization functions will take into account dose of the voxel as the EQD_{RT}.
    - Model parameters
    - Temperature distribution.
  - Strategic goals:
    - Keep dose in OARs and PTV as in the RT only plan
    - Achieve a specific dose level with EQD_{RT} in the GTV (58 Gy)
    - Homogeneous coverage of the GTV.



Implementation

- Robust Optimization:
  - Used for GTV
    - Maintain GTV coverage for lower temperature levels
    - Avoid overdosage for higher temperature levels

HYPERBOOST
Boosting the effect of Radiotherapy

Some Results

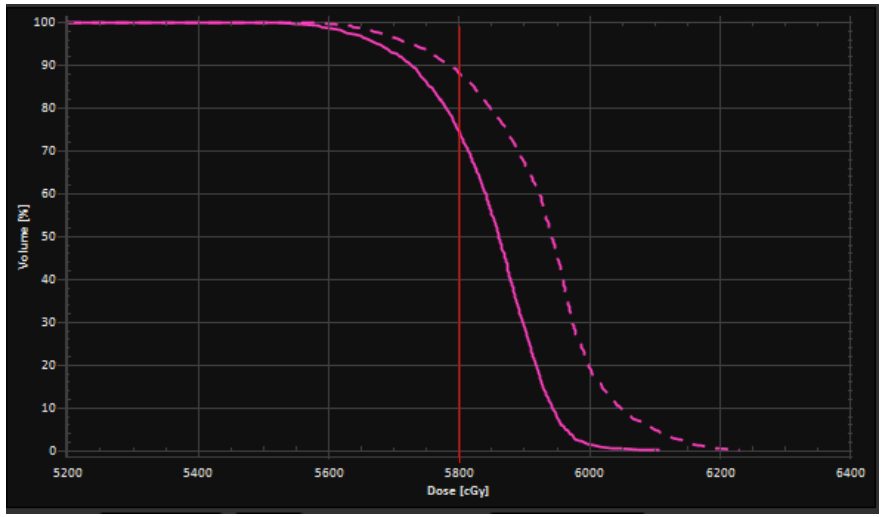
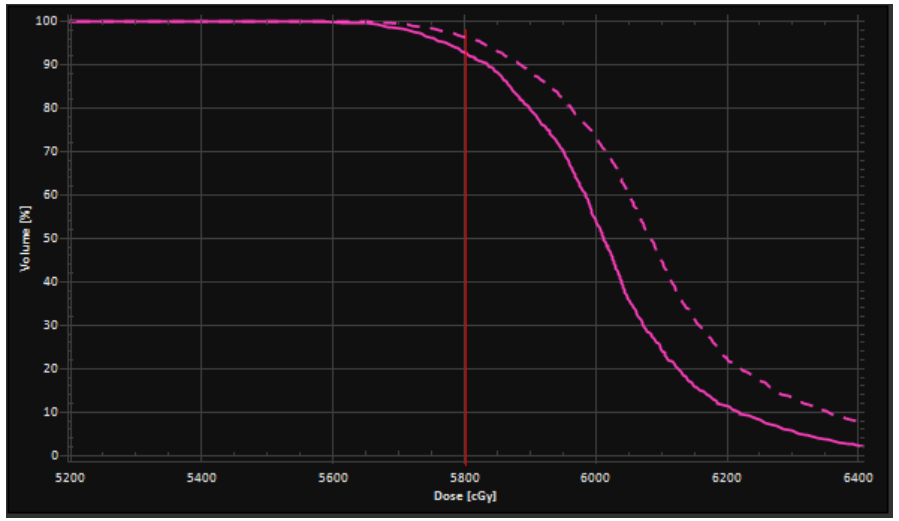
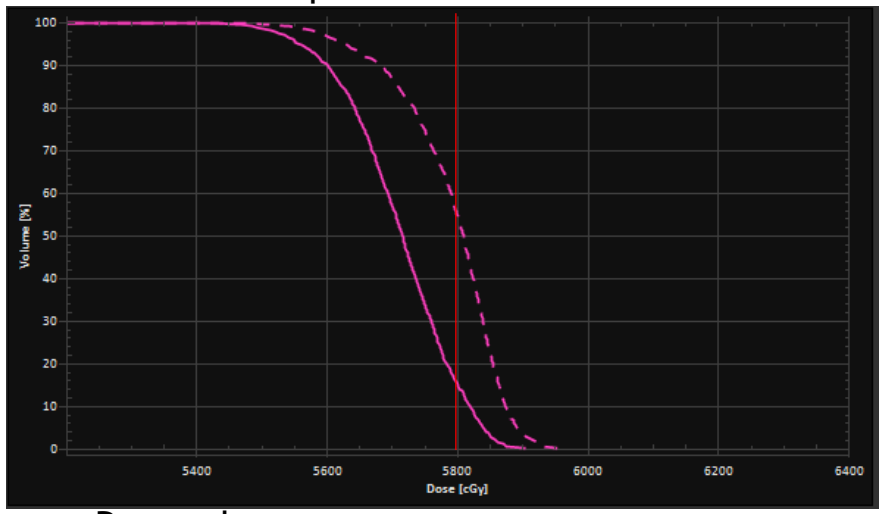
Robust optimization: GTV coverage improves for alternative temperatures at the cost of reduced homogeneity



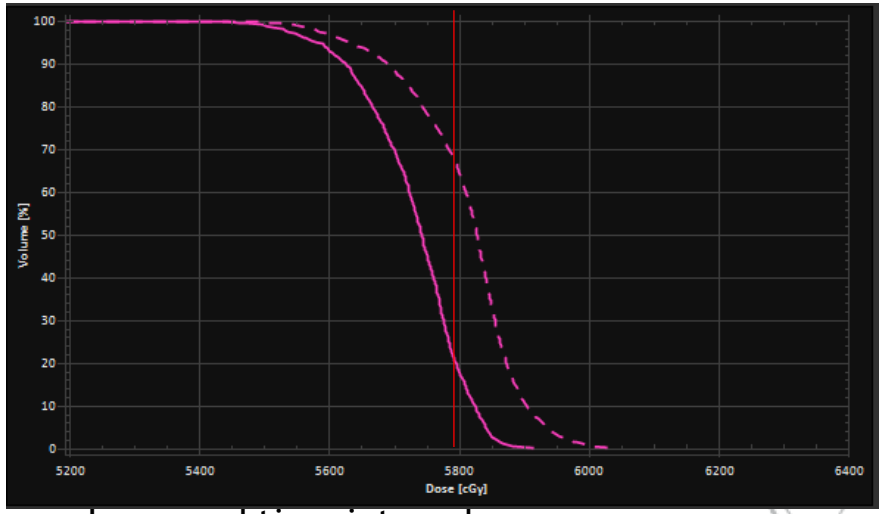
Nominal temperature



Power increase



Power decrease



Increased time interval

EQD_{RT} for the GTV:

— nominal EQD_{RT} optimized plan

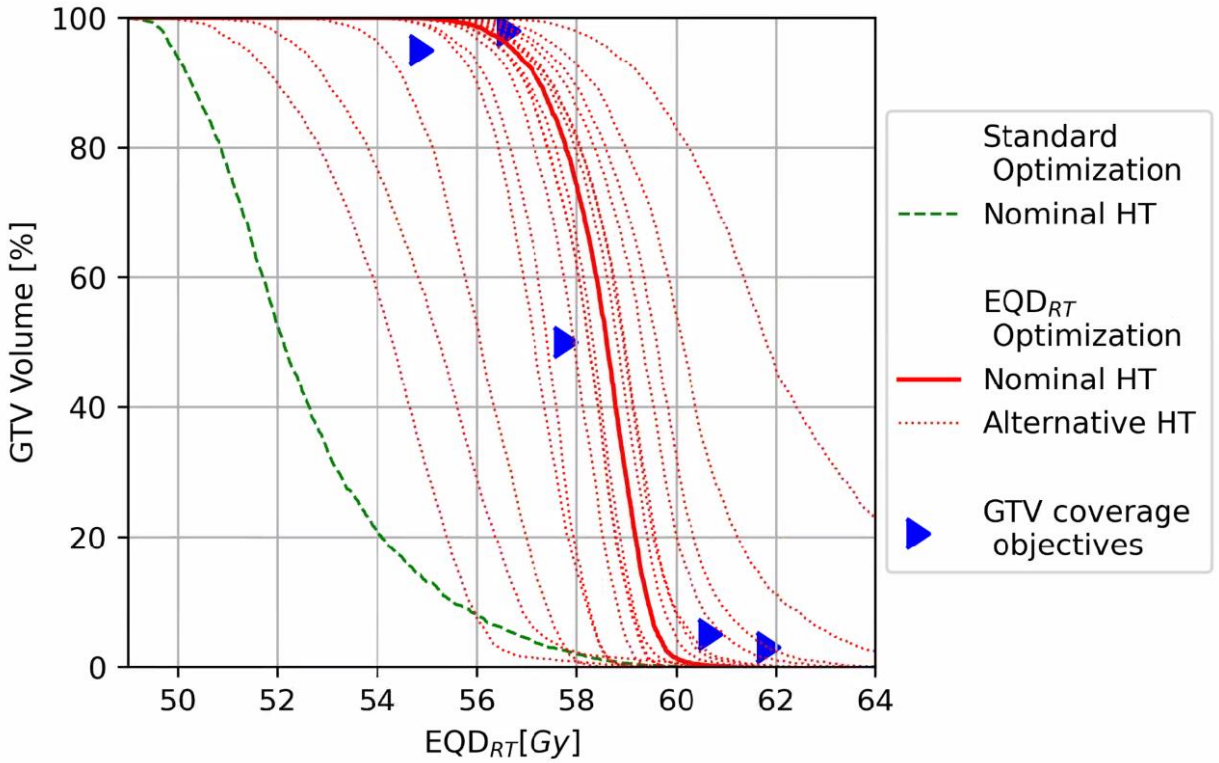
– – robust EQD_{RT} optimized plan

RaySearch Laboratories

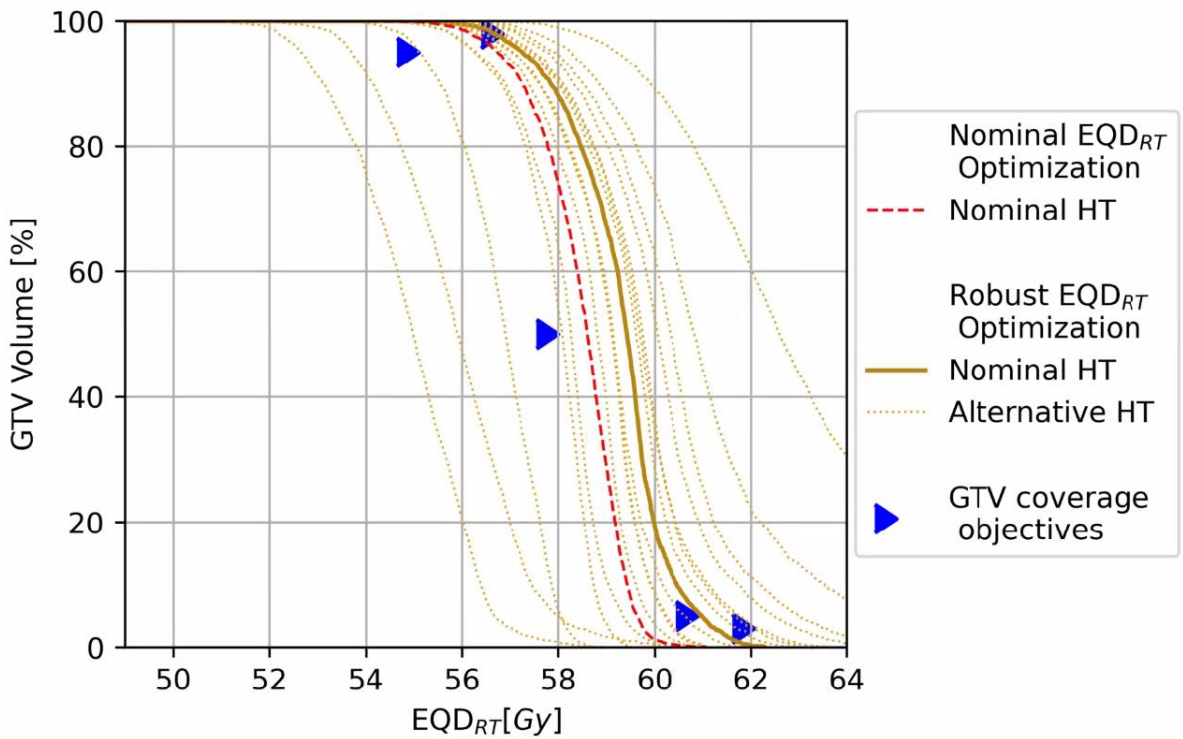
HYPERBOOST
Boosting the effect of Radiotherapy

Some Results

Robustness evaluation for the nominal and 16 alternative temperature scenarios



Nominal EQD_{RT} optimized plan



Robust EQD_{RT} optimized plan

RaySearch Laboratories

HYPERBOOST
Boosting the effect of Radiotherapy

Some Results

Comparison robust vs nominal EQD_{RT} optimized plan:

- Evaluation of clinical goals in the GTV
  - Coverage:
    - EQD_{RT}98%>56.84 Gy
    - EQD_{RT}95%>55.1 Gy
    - EQD_{RT}50%>58 Gy
  - Homogeneity:
    - EQD_{RT}5%<60.9 Gy
    - EQD_{RT}3%<62.06 Gy
    - Homogeneity index at 95% volume > 0.94
- 6 clinical goals evaluated in 17 EQD_{RT} distributions (nominal and 16 alternative) for each plan.

Some Results

Comparison robust vs nominal EQD_{RT} optimized plan:

- Coverage:
  - 53% clinical goals achieved for nominal plan
  - 69% robust
- Homogeneity:
  - 74% clinical goals achieved for nominal plan
  - 55% robust
- GTV coverage improves for alternative temperatures for the robustly optimized plan, at the cost of reduced homogeneity
  - In both the robust and nominal plan, clinical goals are not achieved for some of the alternative scenarios

Summary

- Hyperthermic enhancement of RT dose can be modelled at a voxel level with the linear quadratic model (EQD_{RT}).
- RayStation prototype for (robust) optimization of EQD_{RT} accounts for the temperature distribution and realistic alternative scenarios that could occur as a result of changing device settings in response to hot spots or a change in time interval for logistic reasons.
- EQD_{RT}optimization allows to increase dose level and homogeneity compared to standard planning.
- Robust optimization can increase dose coverage at the cost of reduced homogeneity.

Future work

- Poster ESTRO 2023 (EQD_{RT} optimization and robustness evaluation)
  - Plans optimized for alternative scenarios (not shown here)
- Oral presentation STM 2023 for robust optimization.
- Paper in progress (comparison of optimization strategies)
- Further analysis of optimization strategies and influence of treatment schedule.
- Improvements in the model: normal tissue effects, heterogeneities.

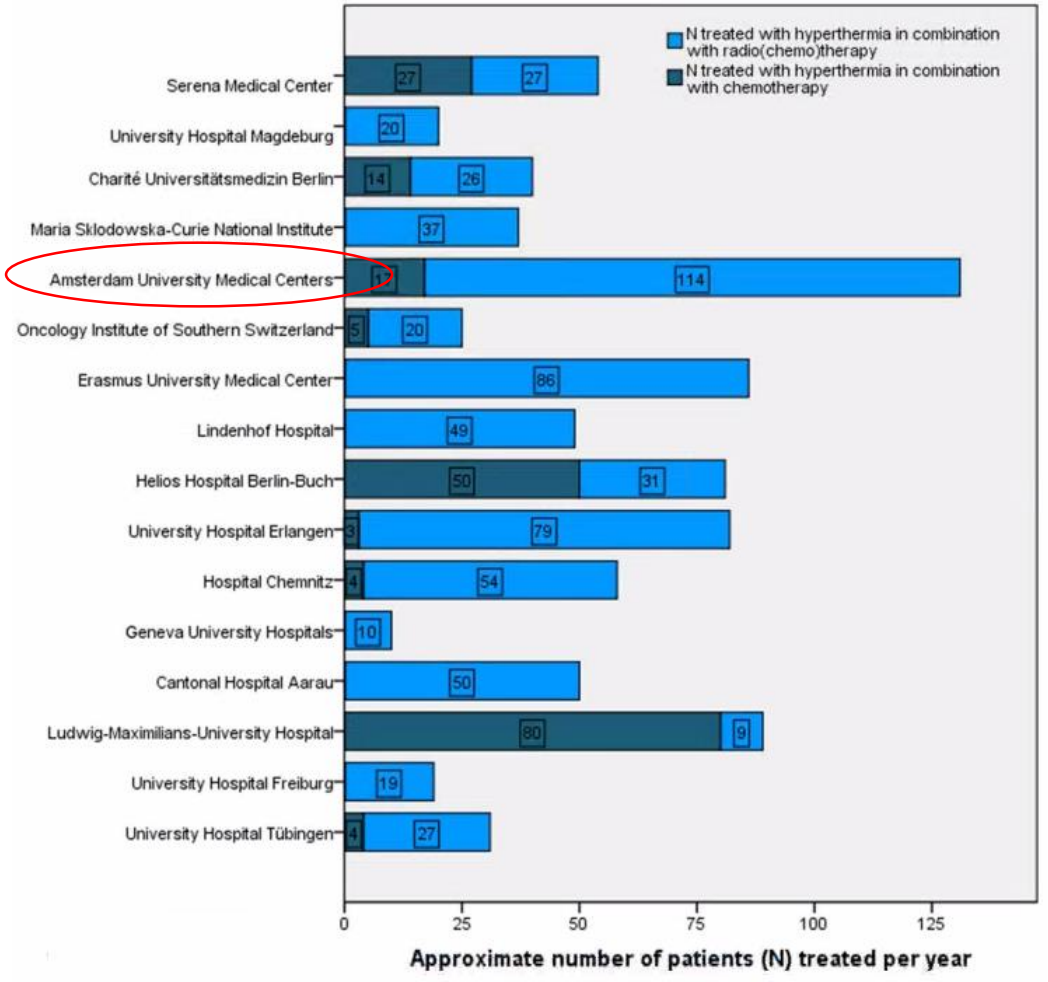
Universitair Medische Centra

Thanks for your attention!
Questions?

Clinical Application of Hyperthermia

- Cervical cancer (Van der Zee, 2002):
  - Increase in OS of ~20% in randomized trial.
  - Radiation toxicity not enhanced by HT
- Amsterdam UMC:
  - HT when contraindication for CT
  - 1 weekly fraction with 5 weekly RT.
- Other indications:
  - Breast (recurrent), head and neck, rectal, bladder, melanoma, NSCLC, glioblastoma, sarcoma and others (Peeken, 2002).
- Reimbursement for some indications



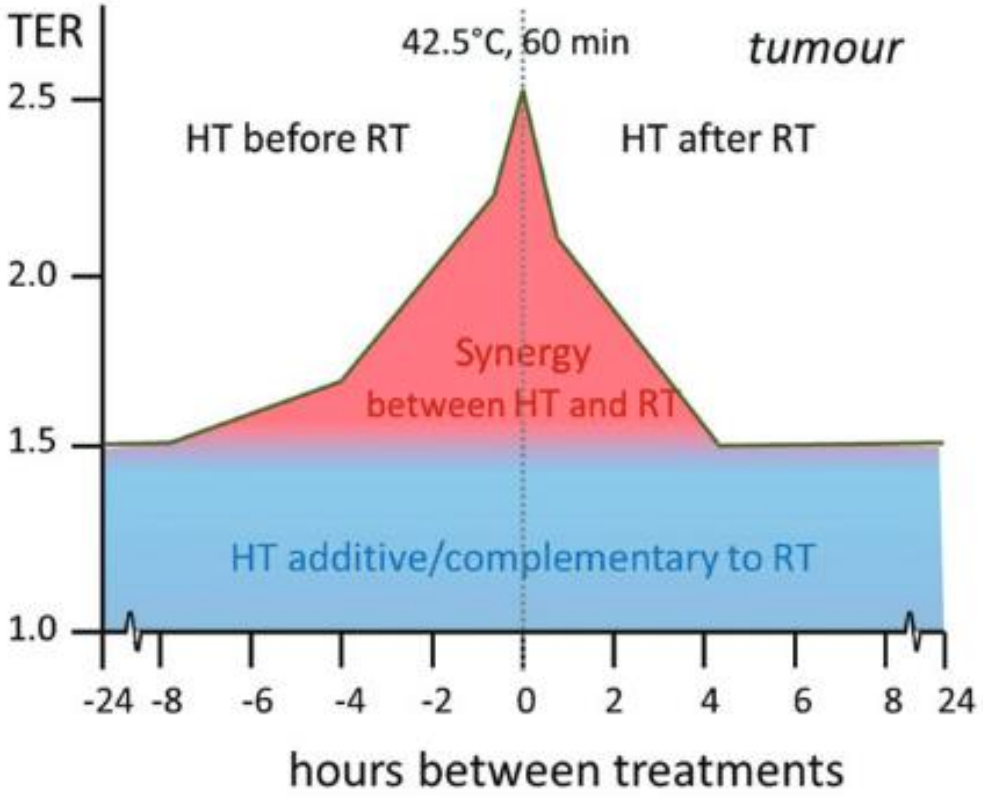
Ademaj et al. Strahlenther Onkol 2022

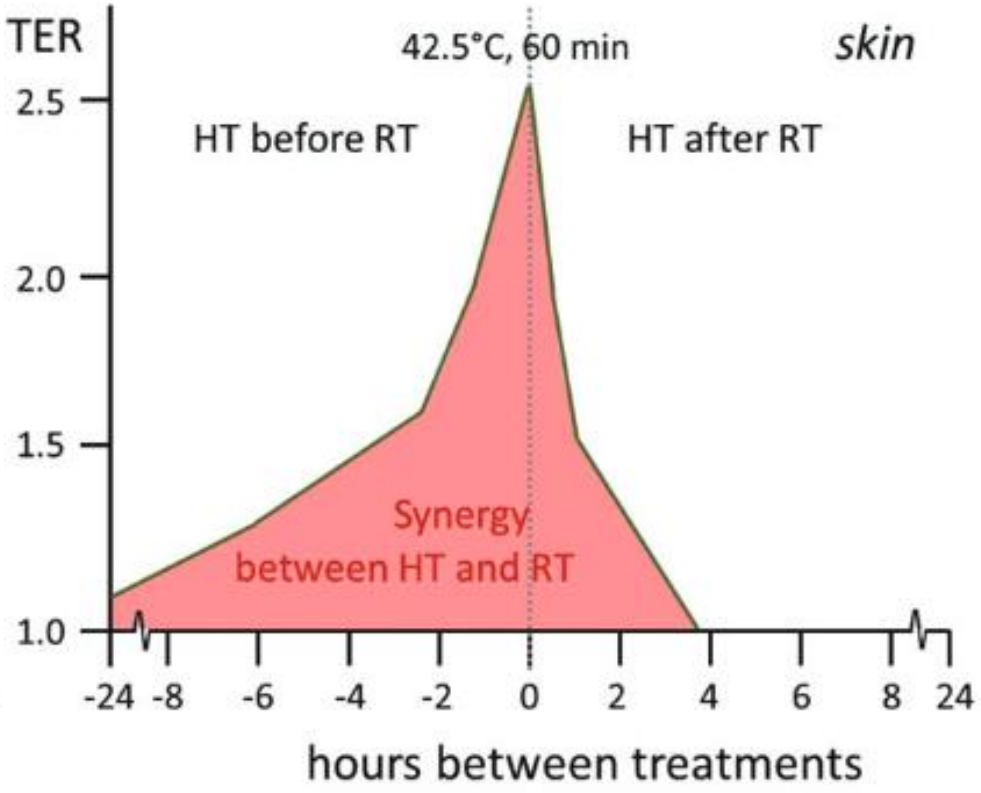
RaySearch Laboratories

HYPERBOOST
Boosting the effect of Radiotherapy

Response to RT + HT treatment

- Thermal Enhancement Ratio (TER): Ratio of the RT dose for RT alone divided by the RT dose for RT + HT with the same cell survival *in vitro*.
- Radiosensitization is tumor sensitive, and time interval is relevant.

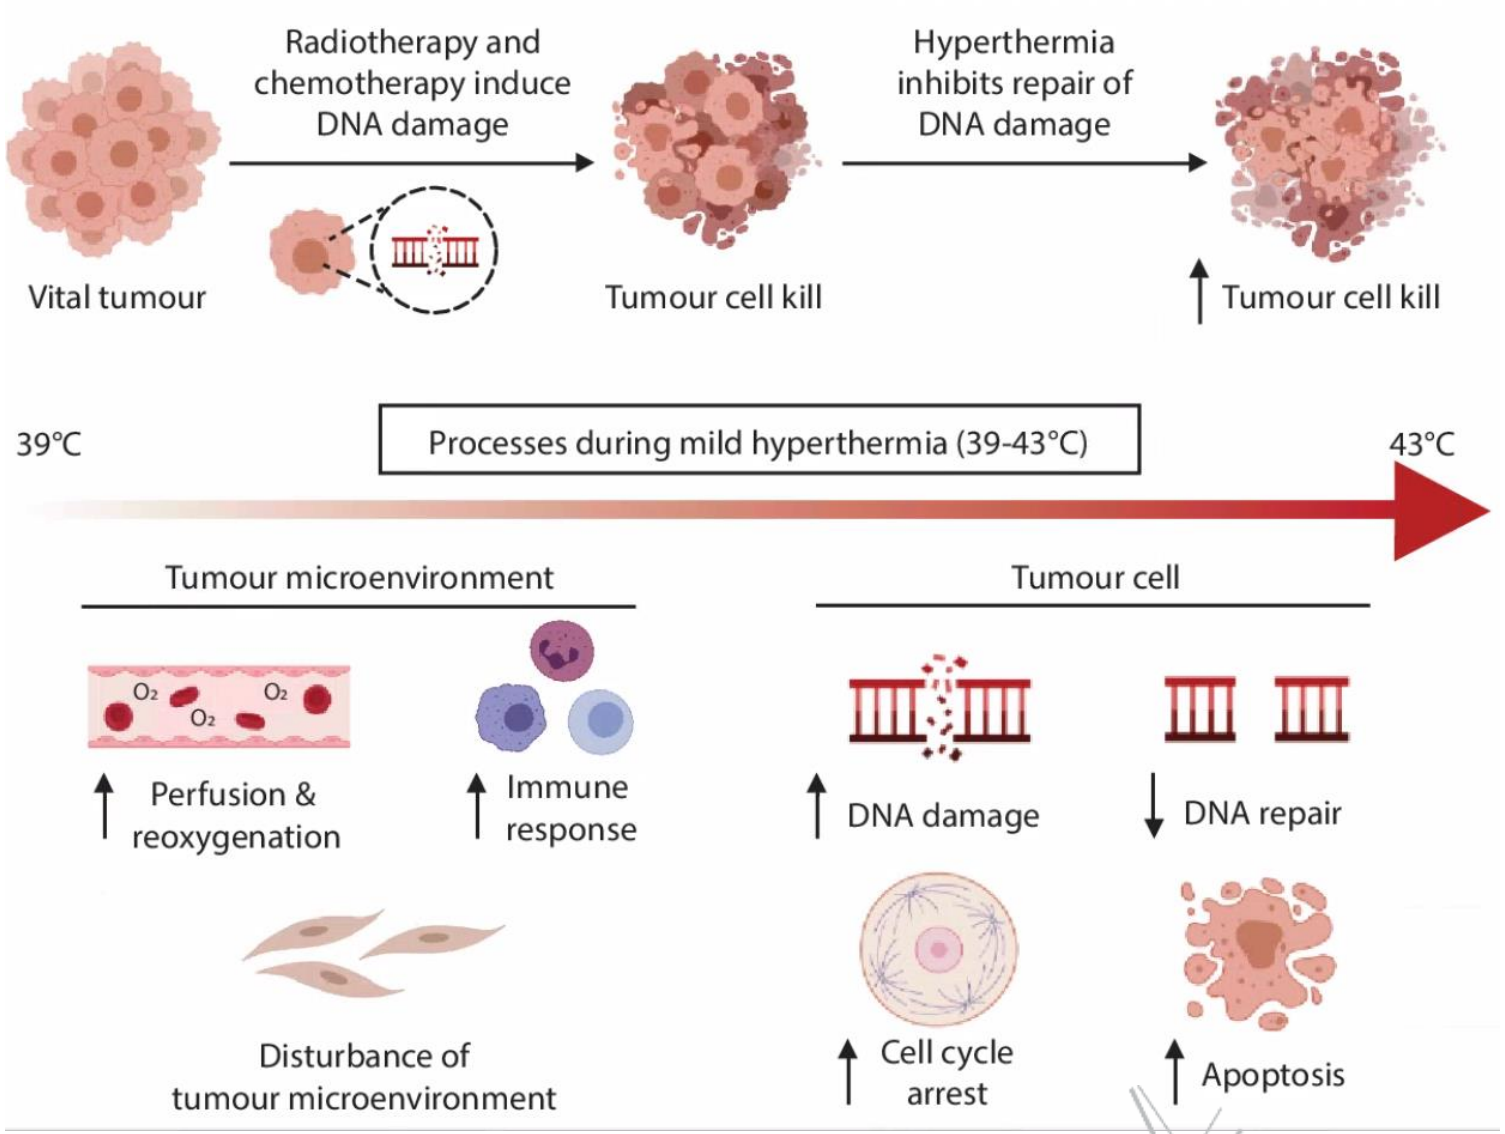




Crezee et al. Int J Hyperth 2016, data from Overgaard, Int J Radiat Oncol Biol Phys 1980

Response to RT + HT treatment

- Complex interaction with cell mechanisms (especially DNA repair) and tumor microenvironment.
- Synergistic effects (depend on RT dose, temperature, duration, time interval)
- Additive effects (independent on RT dose).

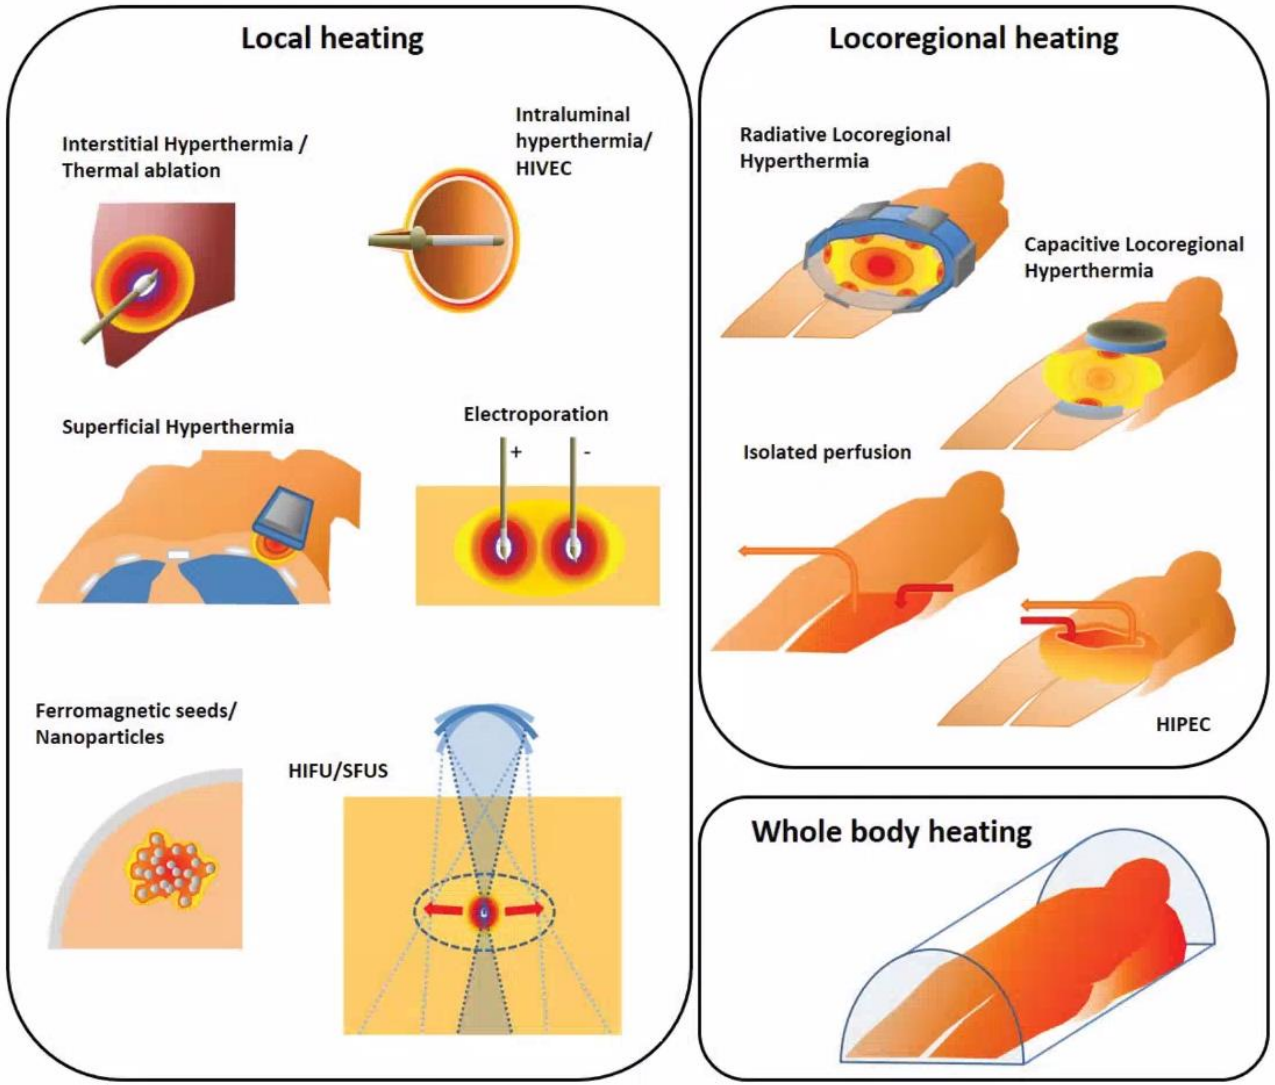


IJff et al. Int J Gynecol Cancer 2021

RaySearch Laboratories

HYPERBOOST
Boosting the effect of Radiotherapy

Thermal Therapy in Oncology



Kok et al. Int J Hyperth 2020

- Hyperthermia: Heating to 39-45°C to induce sensitization to radiotherapy and chemotherapy.
- Thermal ablation: temperatures beyond 50°C to destroy tumor cells directly.
- Different heating techniques and extent, depending on application.
  - Focus on deep locoregional radiative hyperthermia.

RaySearch Laboratories

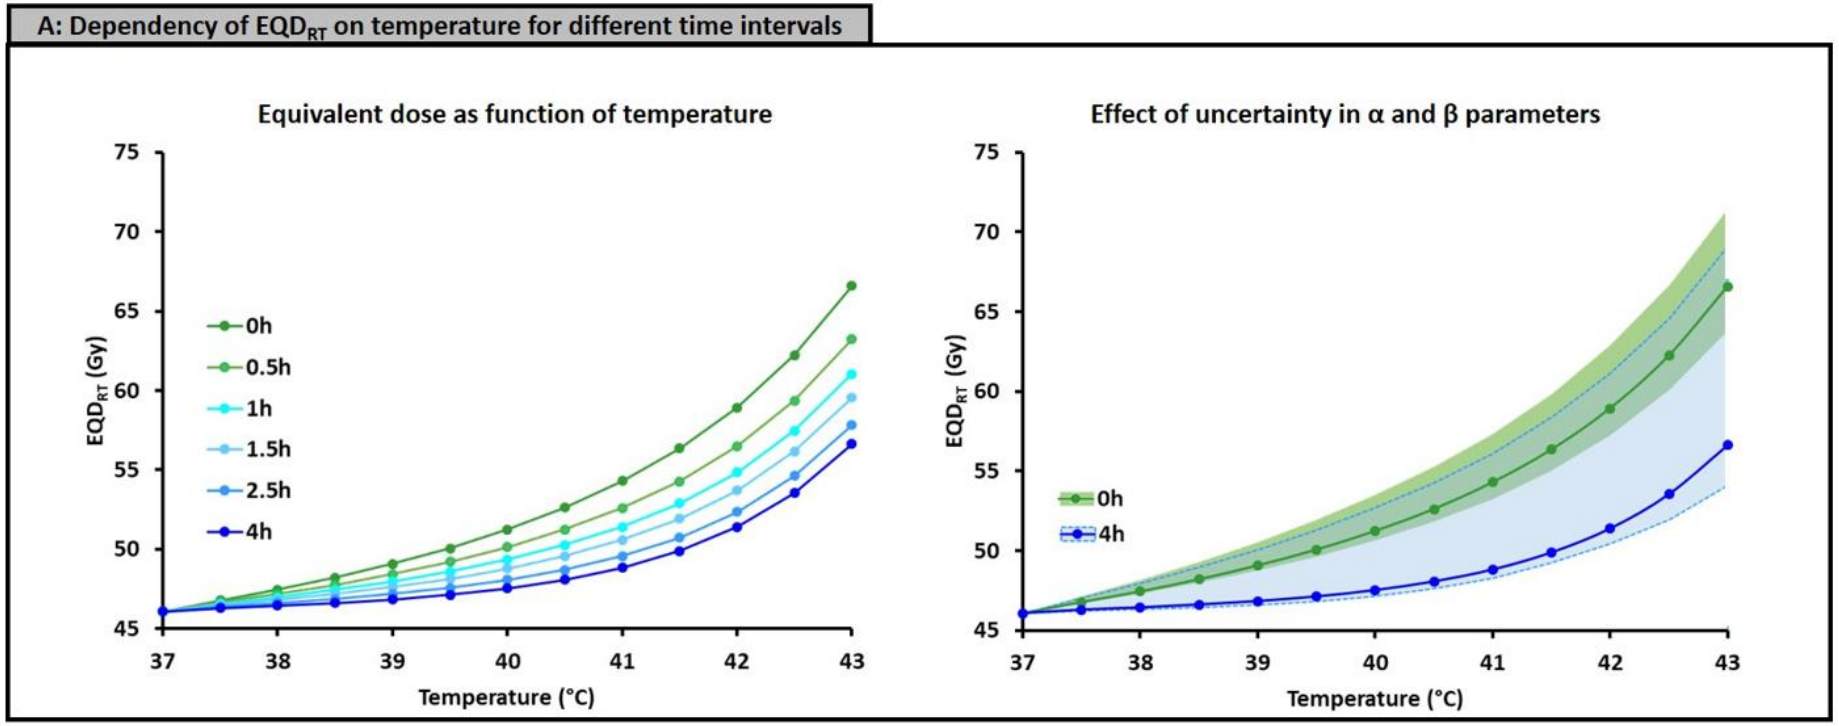
HYPERBOOST
Boosting the effect of Radiotherapy

Equivalent dose for RT + HT

- EQD_{RT} : Dose needed with radiotherapy to have the same effect than the combined treatment.
- Derived from EQD concept
  - α and ß function of temperature and time Interval between radiotherapy and hyperthermia
- Parameters from cell survival assays.
- Calculation at a voxel level
  - EQD_{RT} distribution, DVHs, etc.
- EQD_{RT} for the whole treatment:
  - Take into account fractions RT + HT, fractions only RT

Modeling the combined treatment

- Model limitations:
  - Tumor homogeneous in sensitivity
    - Not taking into account oxygen levels, vascularization, etc.
  - Mostly DNA repair inhibition (modified LQM parameters) and direct cell kill (temperature dependent term).
  - Normal tissue: No direct cell kill and fastest decay for synergistic effect.



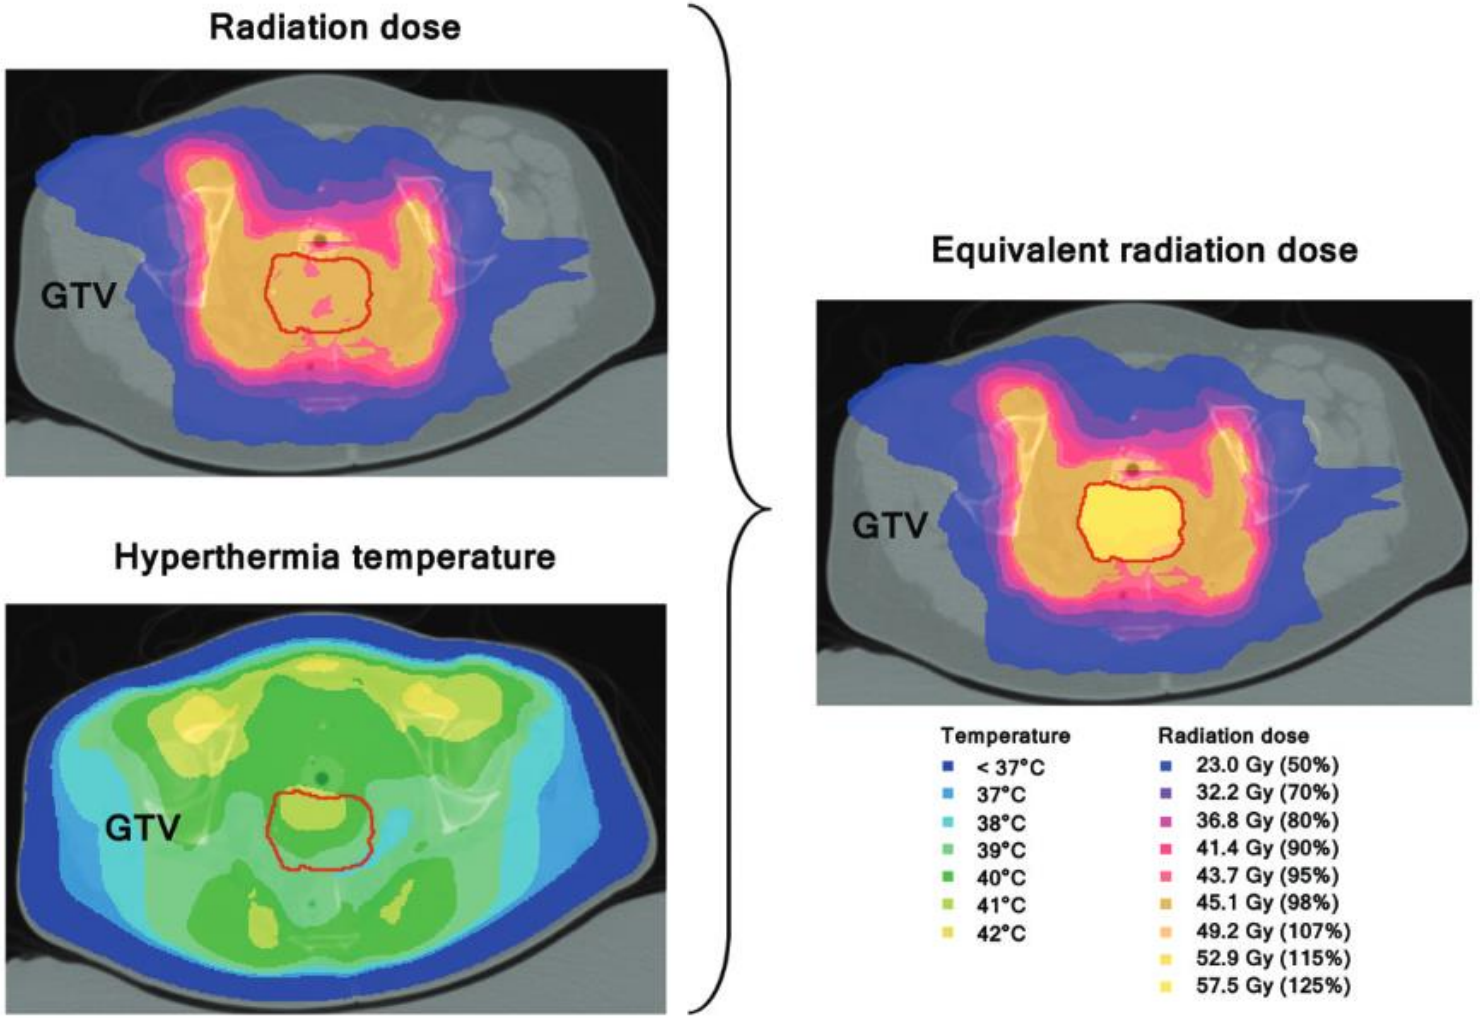
EQD_{RT} for a scheme of 23 fractions of 2 Gy with weekly hyperthermia (homogeneous temperature)

Kok et al. Int J Radiat Oncol Biol Phys 2022

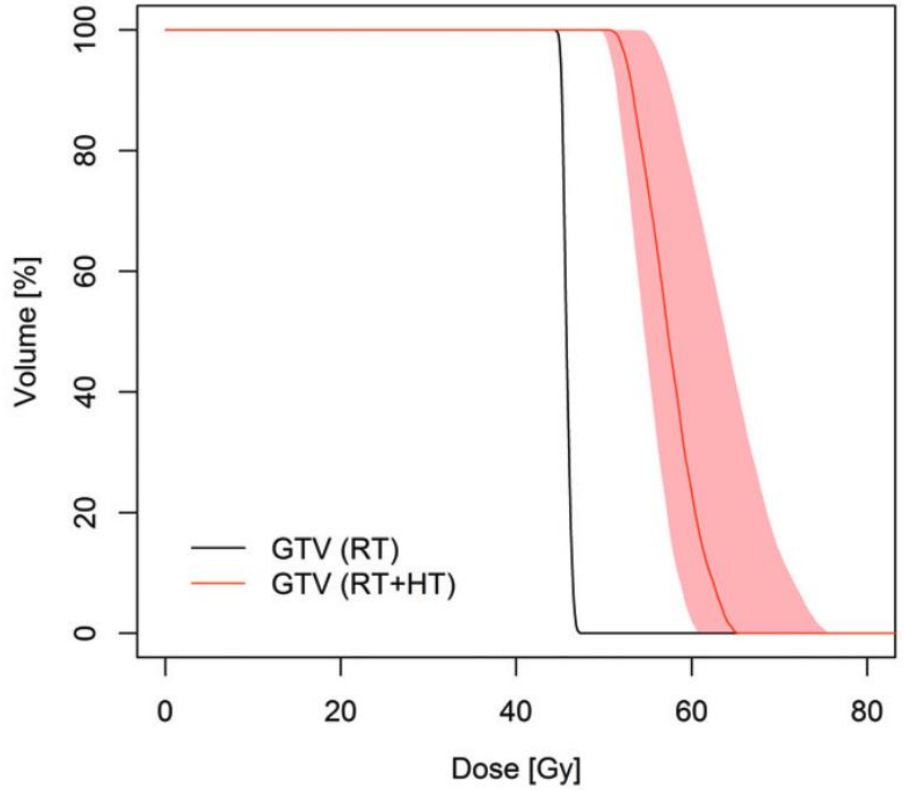
RaySearch Laboratories

HYPERBOOST
Boosting the effect of Radiotherapy

Equivalent dose for RT-HT



- The temperature distribution can be used to calculate an equivalent radiation dose voxel by voxel.



Van Leeuwen et al. Int J Hyperth 2018

RaySearch Laboratories

HYPERBOOST
Boosting the effect of Radiotherapy

Effects of the combined treatment

- Modeling is not the same for additive and synergistic effects of hyperthermia and radiotherapy.
- Time and spatial dependence (heterogeneity, heat response).

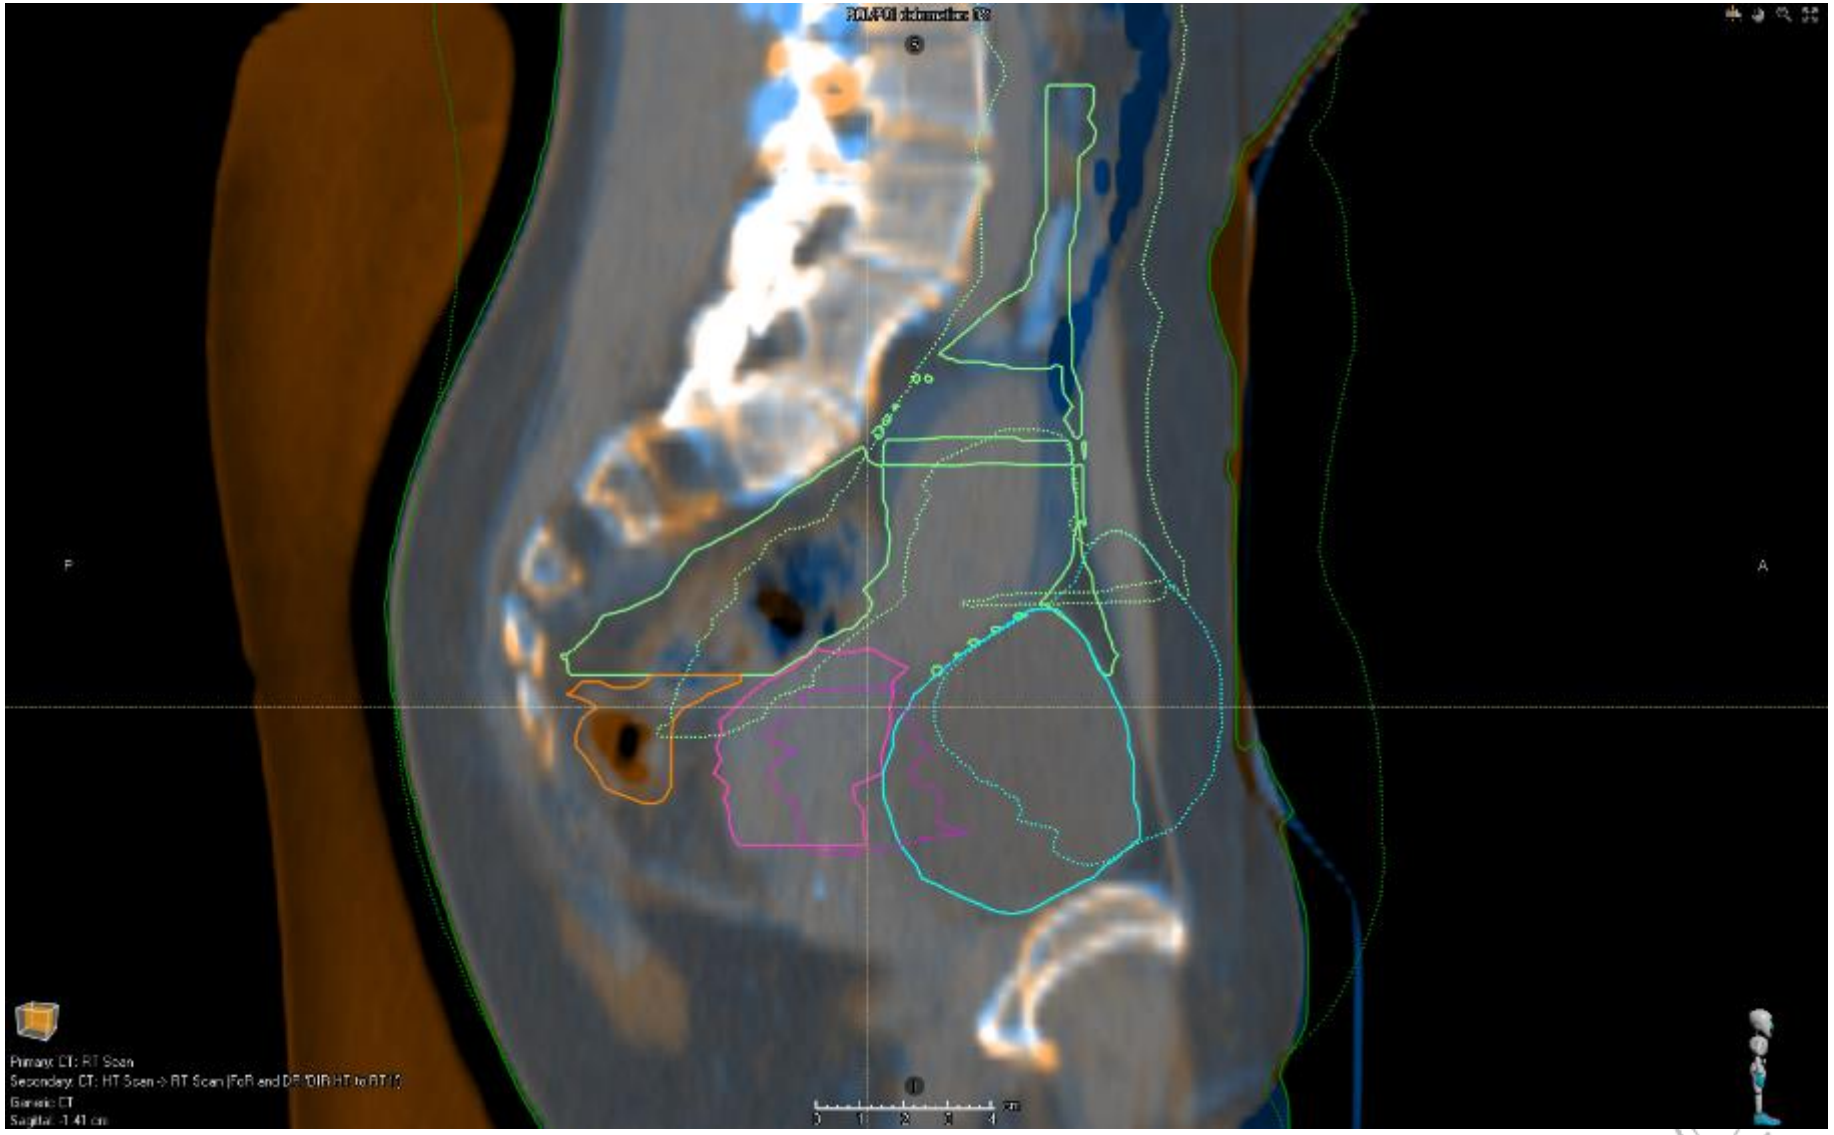
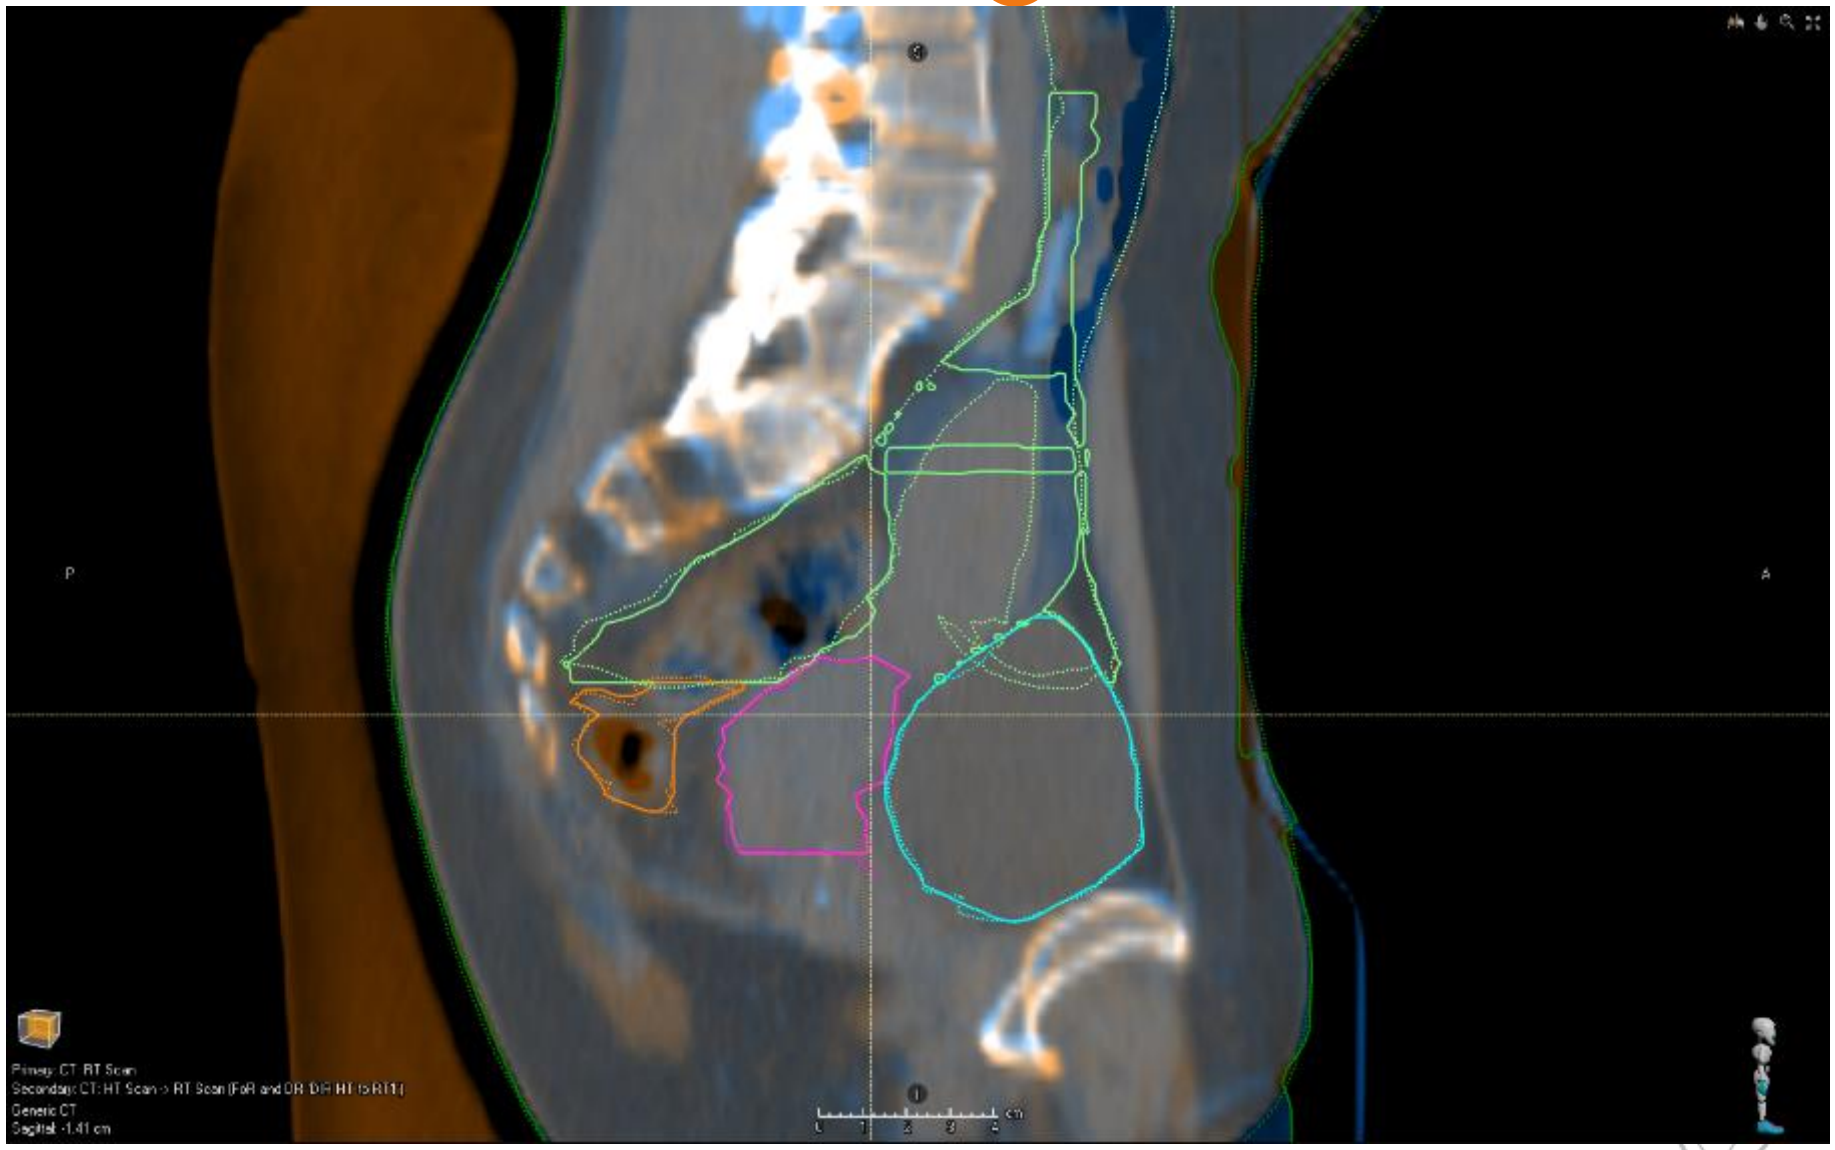
Implementation in RayStation



Deformed CT,
undeformed ROIs

Implementation in RayStation



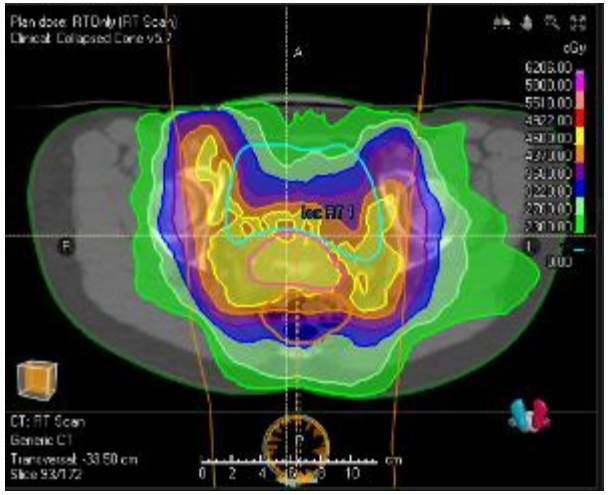
Deformed CT,
deformed ROIs

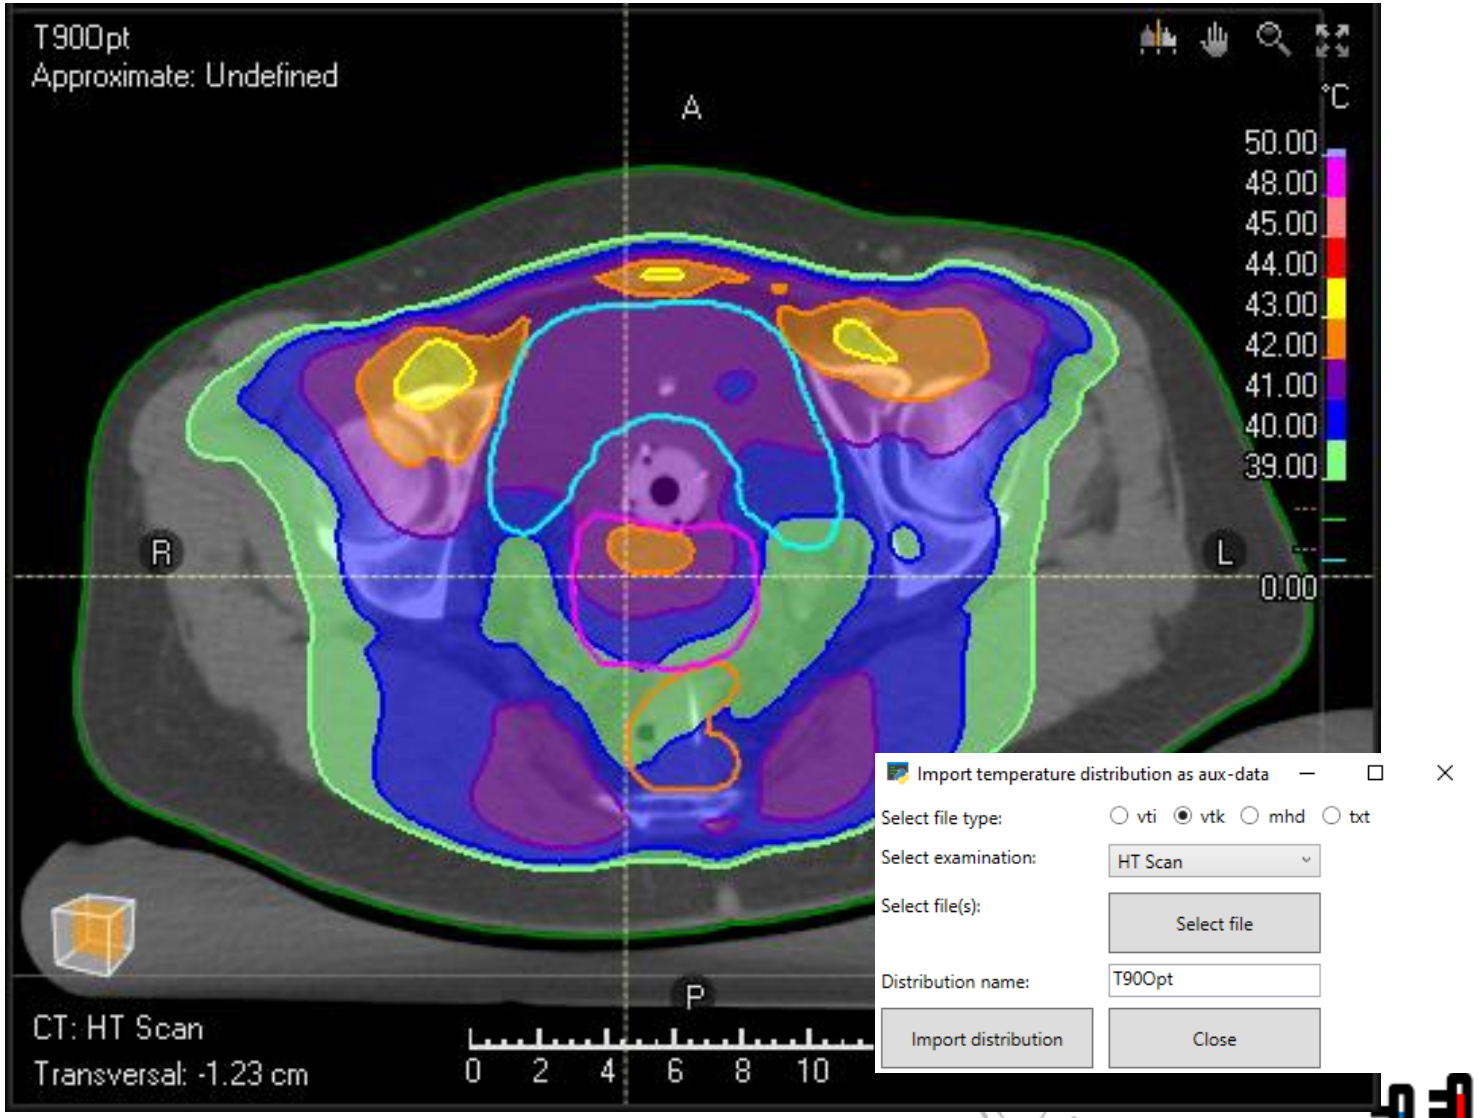
RaySearch Laboratories

HYPERBOOST
Boosting the effect of Radiotherapy

Implementation

- Nominal and alternative temperature distributions imported to RayStation as .vtk (Python scripting)
  - Auxiliary dose associated to the HT scan.
- Standard VMAT plan
  - 23 fractions of 2 Gy to PTV
  - For comparison and reference of dose to OARs.





RaySearch Laboratories

HYPERBOOST
Boosting the effect of Radiotherapy

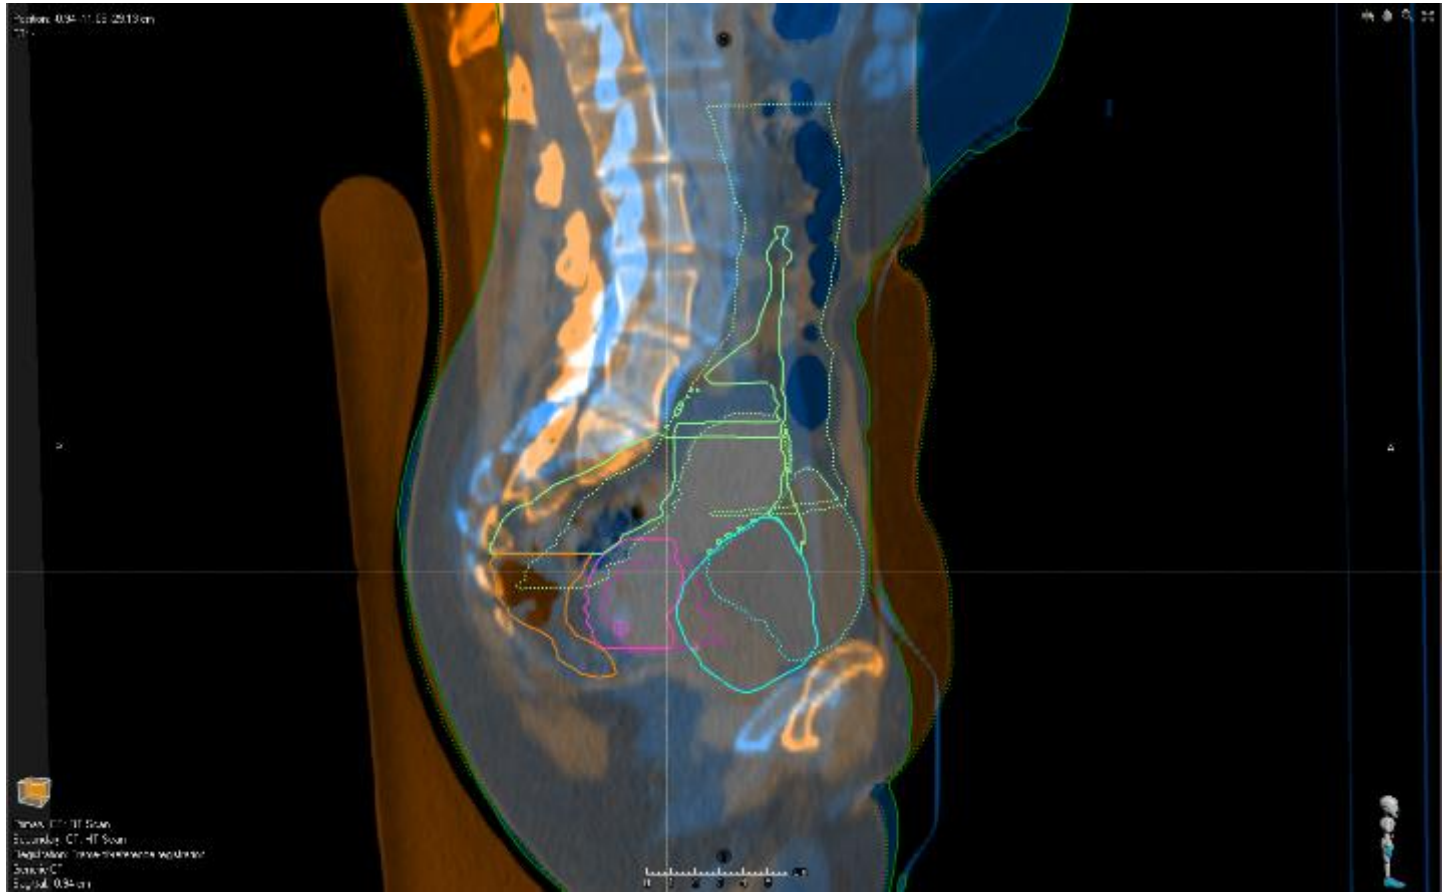
Implementation

- Deformable registration, target HT scan, reference RT scan
  - HT scan supine, RT scan prone
  - HT scan with water bolus, RT scan on flat couch
  - HT scan with empty bladder, RT full bladder.

Reference image set:	CT: RT Scan [20 Aug 2014, 10:44:42 (hr:min:sec)]
Target image set:	CT: HT Scan [12 Sep 2014, 15:16:03 (hr:min:sec)]
Group type:	Hybrid
Discard image information:	No
Deformation strategy:	Default
Similarity measure:	Correlation coefficient
Algorithm:	Hybrid GPU, v3.1
Created on:	15 Nov 2022, 13:21:35 (hr:min:sec)
Default for dose deformation:	No
Approved:	No
Inverted elements:	No

Controlling ROI(s):

Color	Name
	bowel_bag_DIR
	rectum_DIR
	bladder_DIR
	gtv_DIR



Primary RT scan (blue), secondary HT scan (orange)

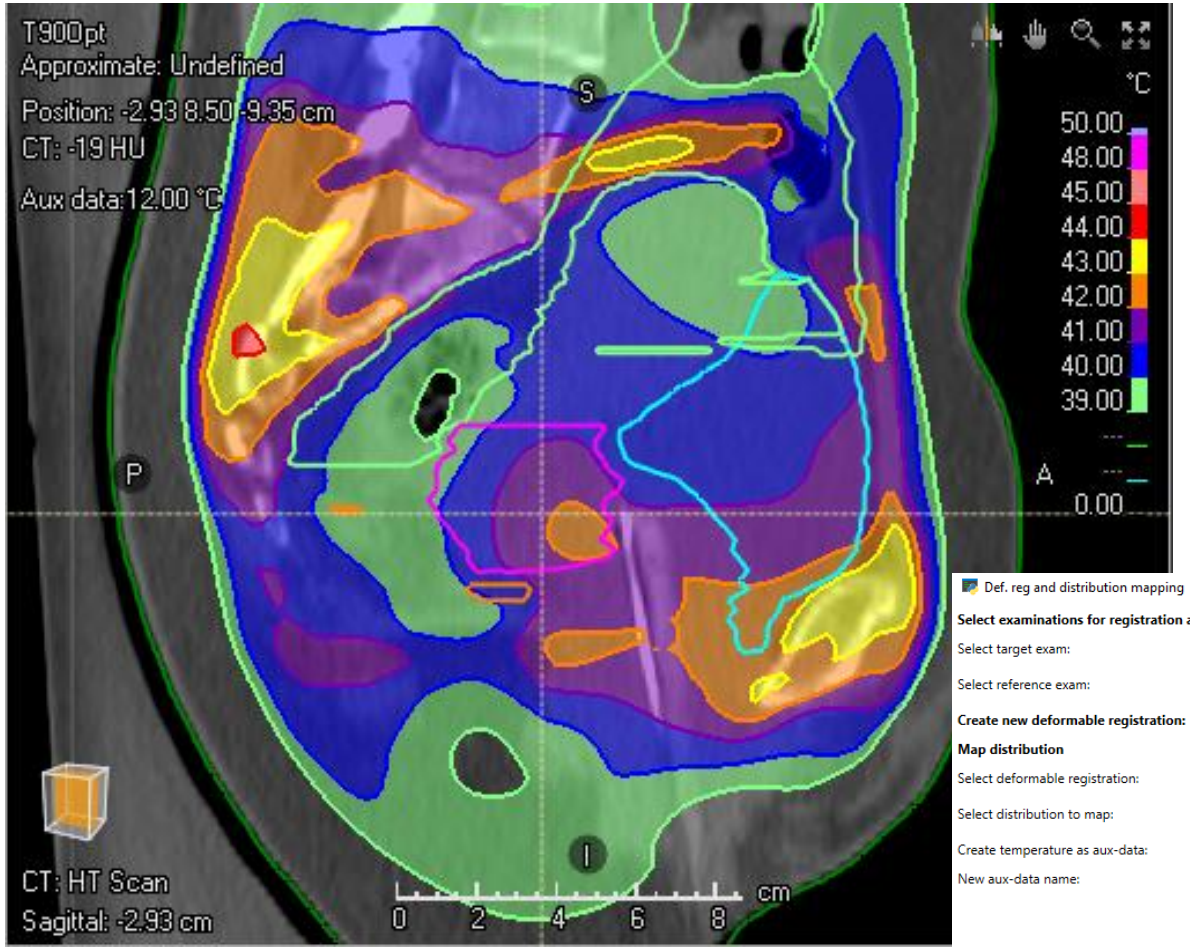
RaySearch Laboratories

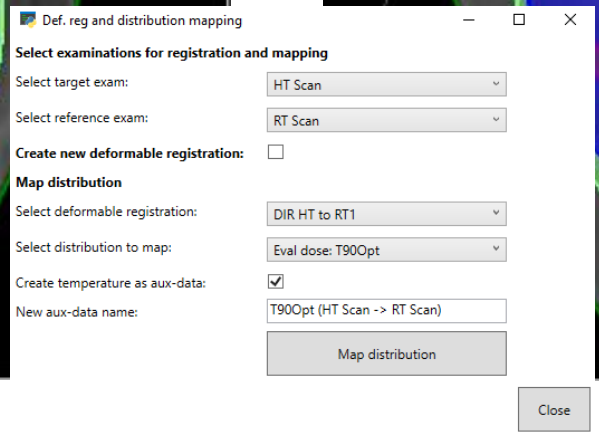
HYPERBOOST
Boosting the effect of Radiotherapy

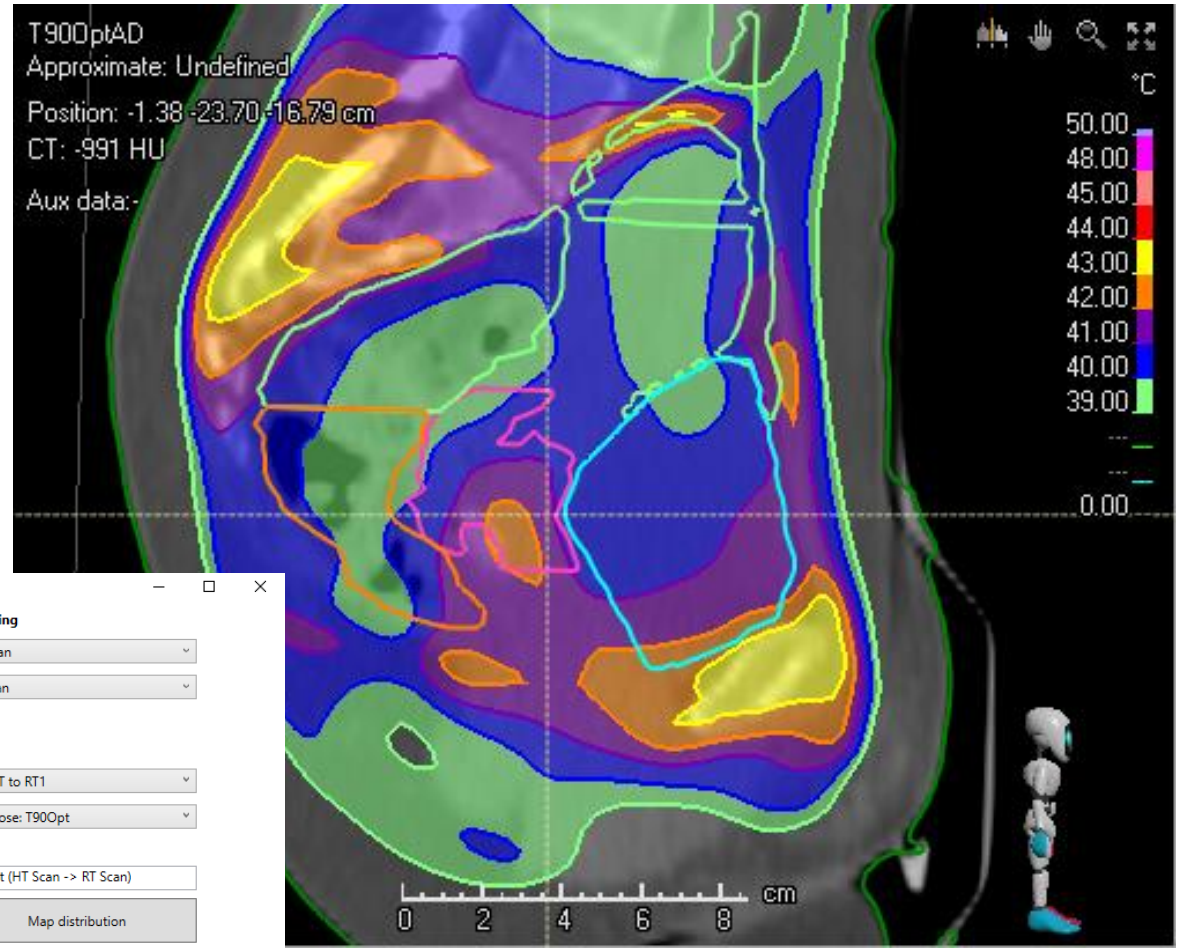
Implementation

- Temperature distribution deformed to RT scan (Python scripting)

RT scan, deformed temperature







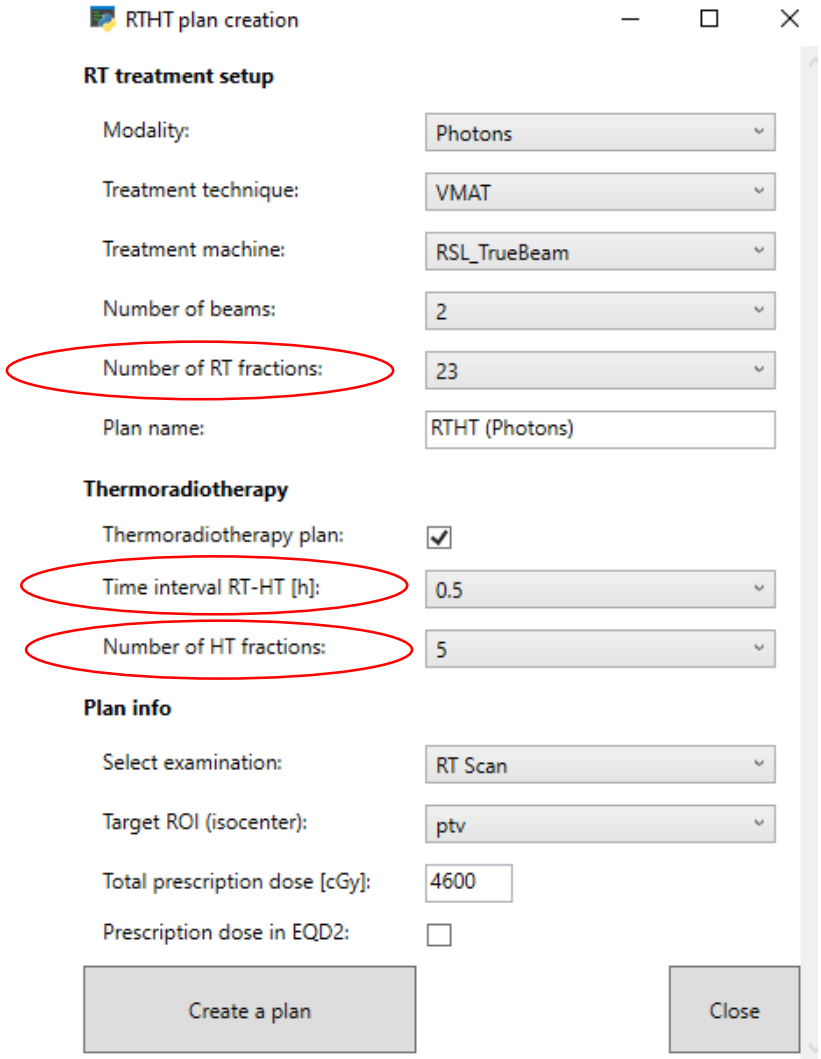
HT scan, original temperature

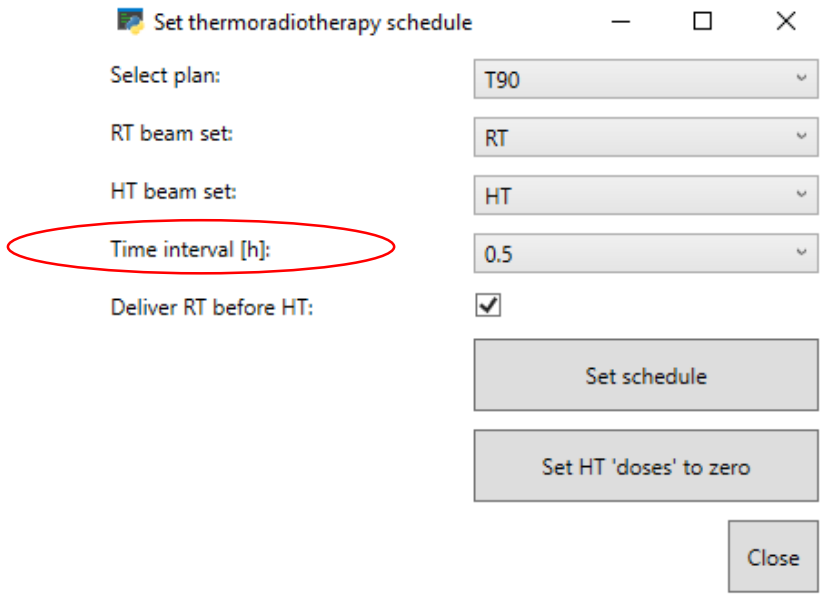
RaySearch Laboratories

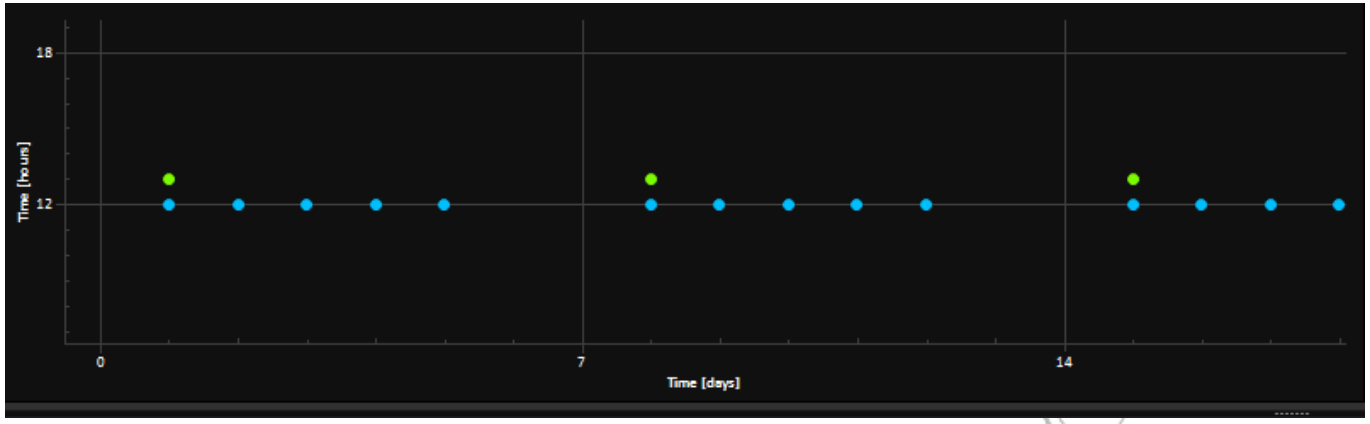
HYPERBOOST
Boosting the effect of Radiotherapy

Implementation

- Schedule: HT weekly (mock beam set), time interval with RT is relevant for optimization (Python scripting)







RaySearch Laboratories

HYPERBOOST
Boosting the effect of Radiotherapy

Implementation

- Optimization: Combination of functions for dose and for EQD_{RT}.

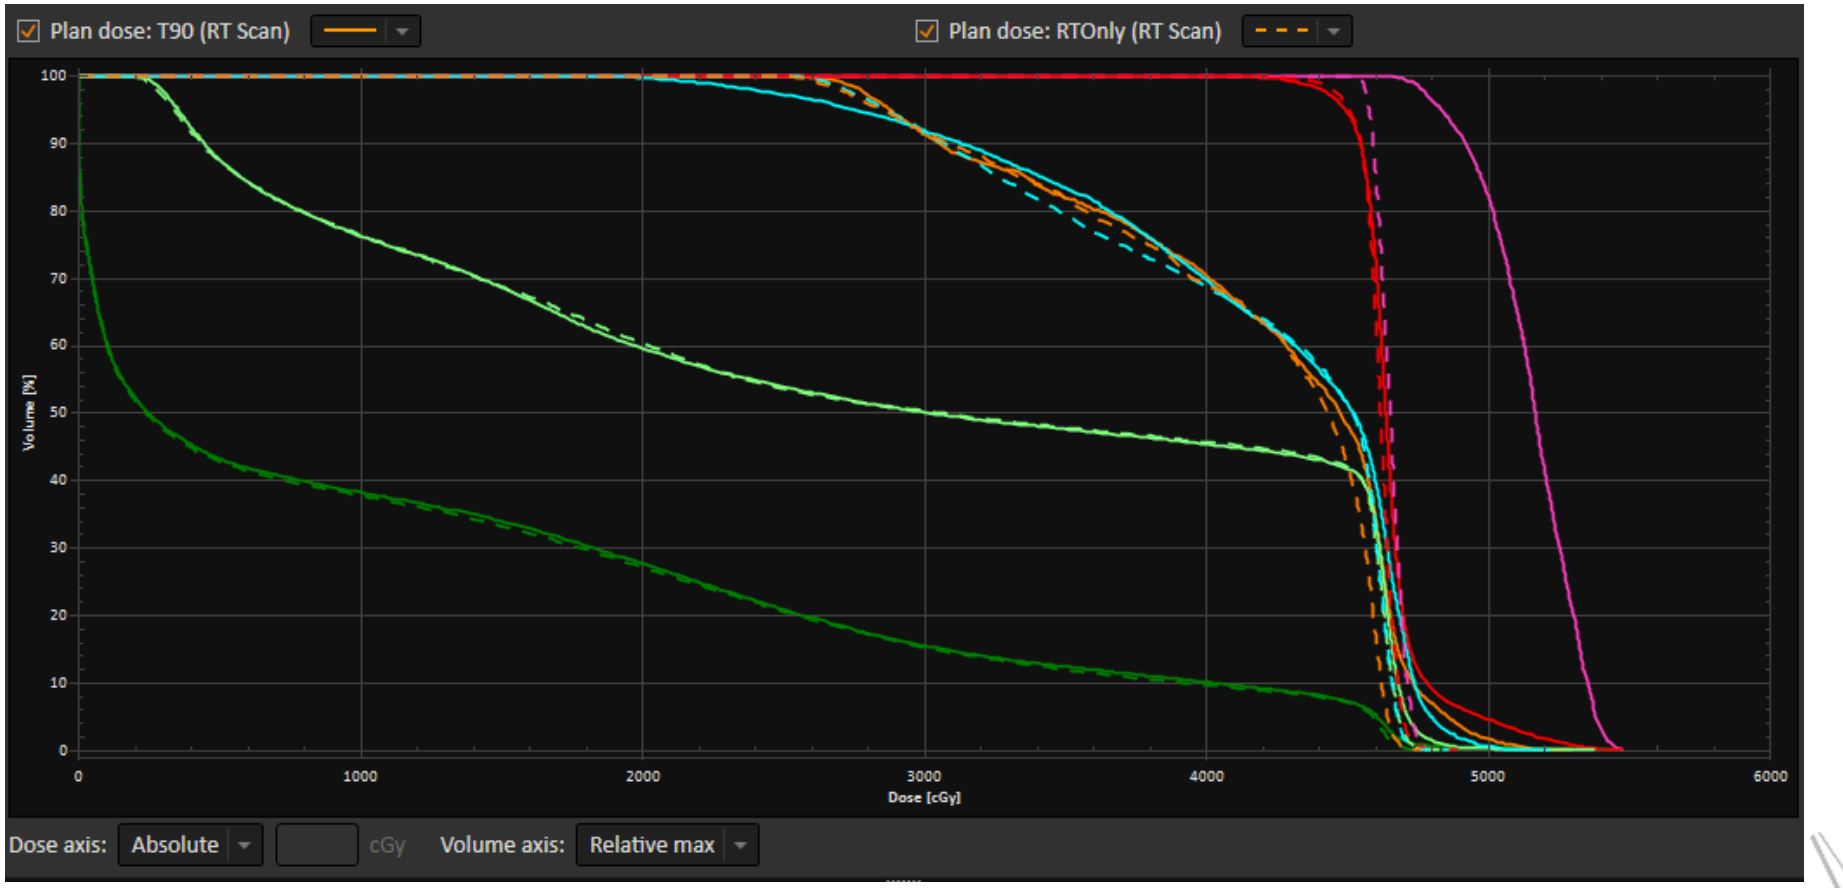
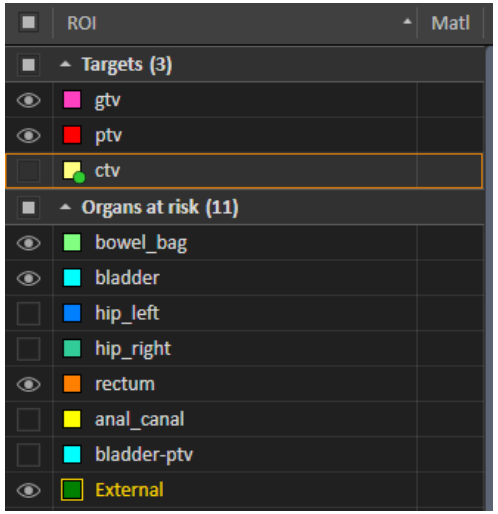
RaySearch Laboratories

HYPERBOOST
Boosting the effect of Radiotherapy

Implementation

- Optimization:
  - Shape of DVHs for OARs and PTV is kept, but max doses are increased.
  - GTV coverage is heterogeneous.



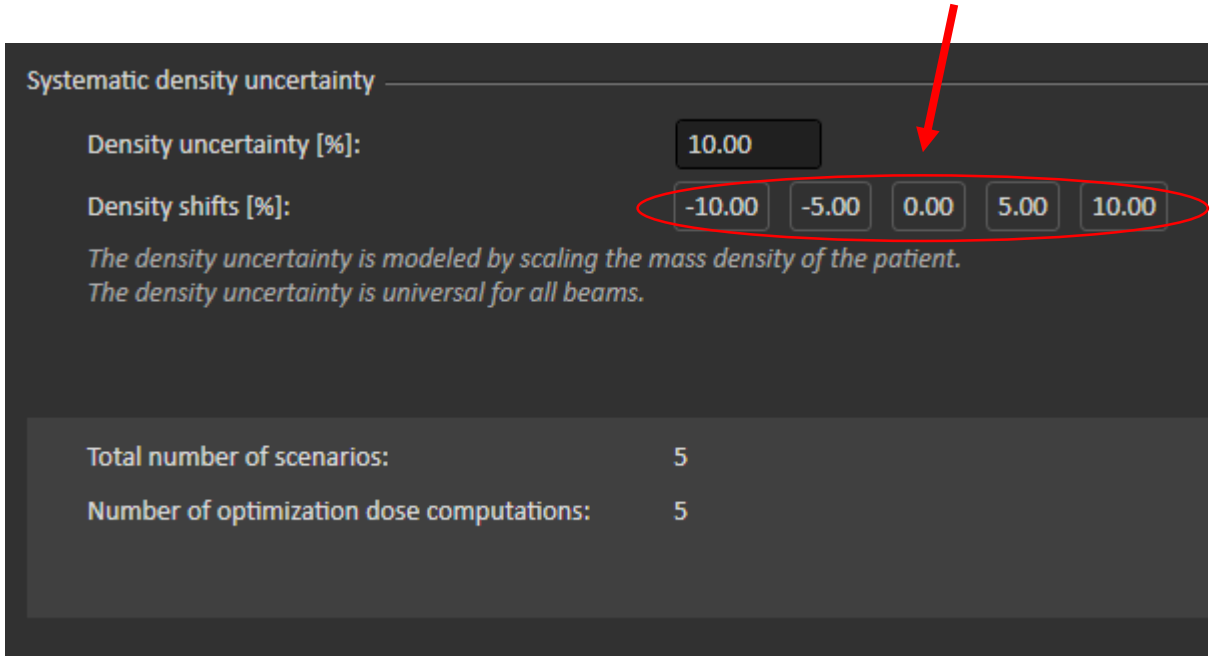


Dose (not EQD_{RT})
EQD_{RT} optimized plan (solid) and standard plan (dashed)

Implementation

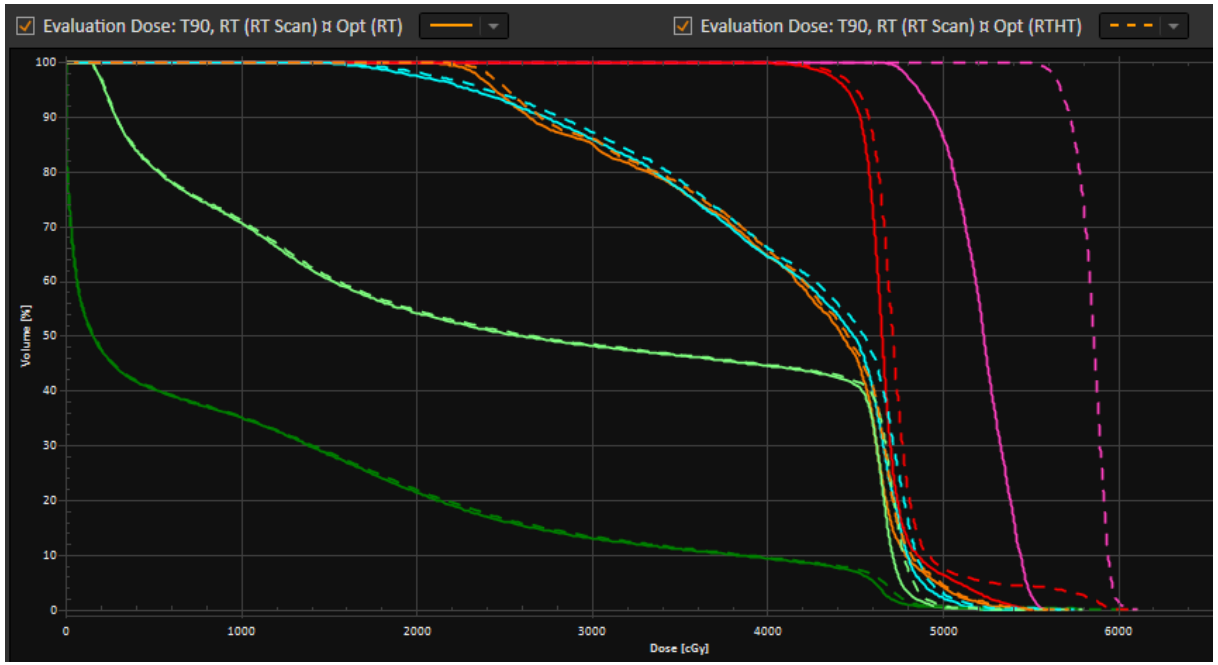
- Robust Optimization:
  - Minimax robust framework in RayStation
    - Alternative temperature scenarios instead of setup/density errors.
  - Alternative temperatures:
    - 16 scenarios created and used for robustness evaluation.
      - Steering adjustment (with constant total power).
      - Power increase/decrease.
      - Increased time interval.
    - 4 of these used in robust optimization

Temperature scenarios



Implementation

- EQD_{RT}: Created as an evaluation dose using Python scripting with ROI specific model parameters.
  - Effect is much larger in GTV than in OARs



EQD_{RT}: EQD_{RT} optimized plan (dashed) and standard plan (solid)

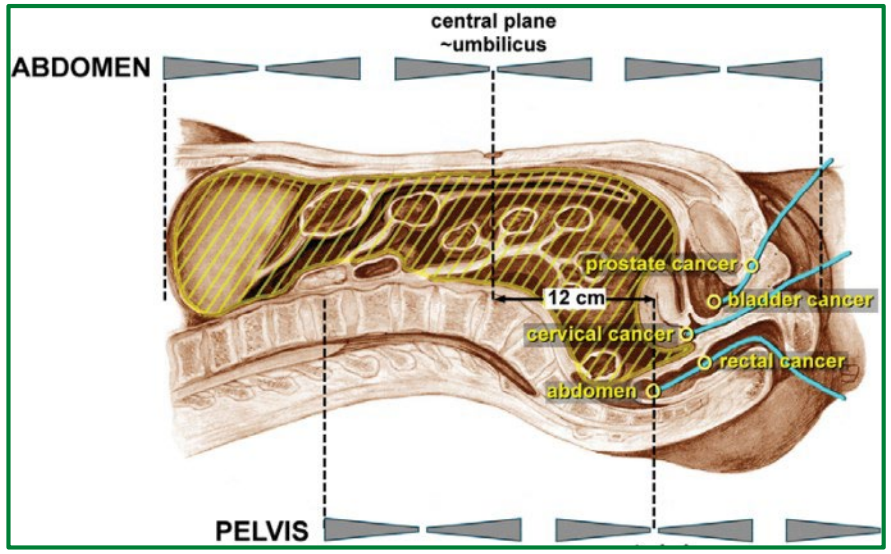
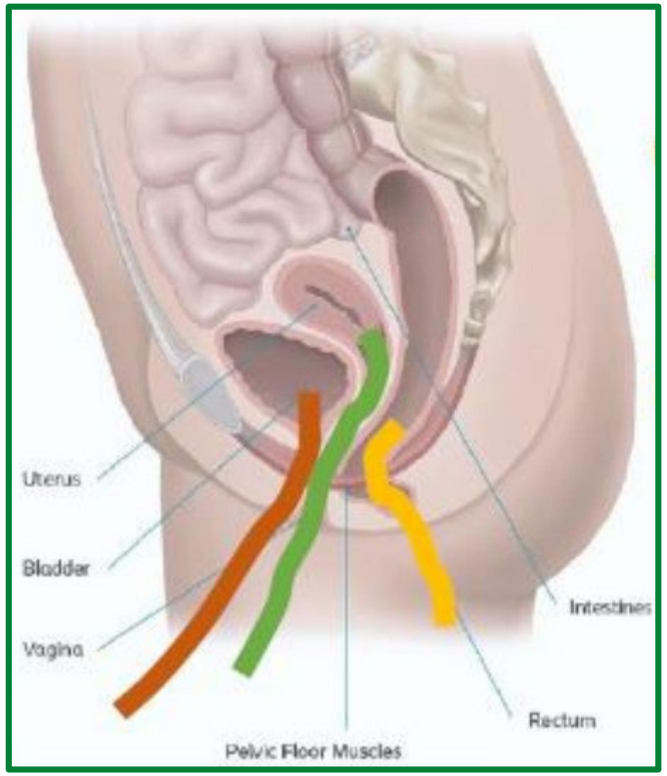
Thermal monitoring during deep pelvic-regional Hyperthermia

- Invasive Thermometry
  -Intratumoral
- Min.Invasive
  -Intraluminal
- Tumor-related reference points





- Disadvantages :

Limited spatial information on temperature distribution + discomfort for the patients (sometimes refusal)[3]

Solution : Magnetic Resonance Imaging or Magnetic Resonance Thermometry (MRT)

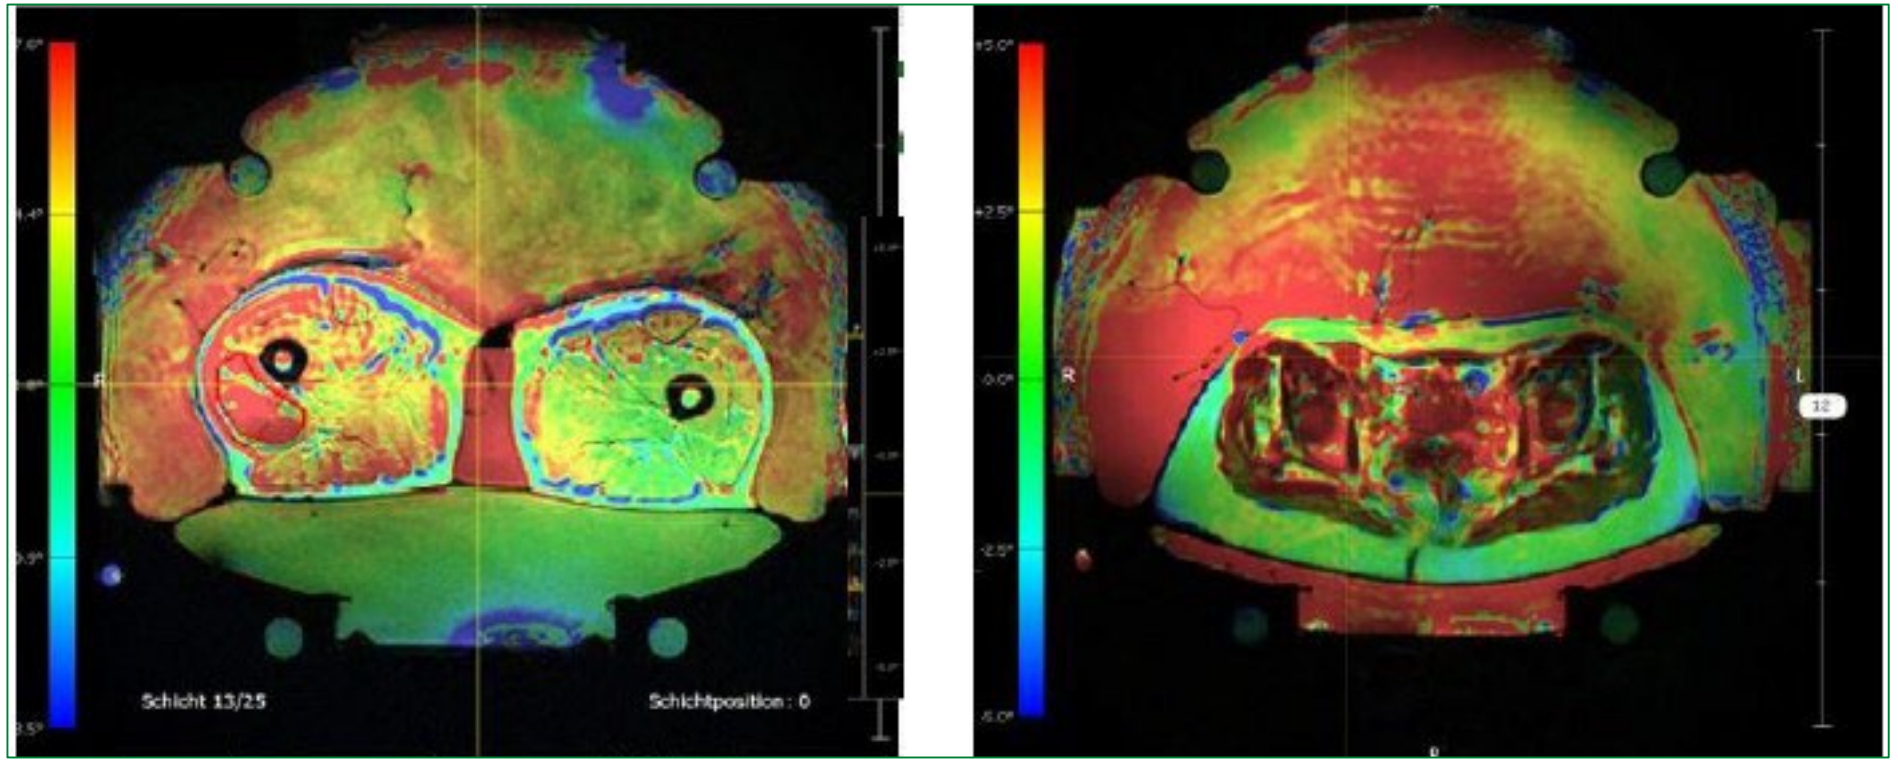
LMU KLINIKUM



Challenges of MRT[4]

- PRF method: linearity, largely tissue type indepedent :

1) Spatio-temporal Static Magnetic field alterations or field drift

2) Intra / Inter –scan motion

3) Temperature induced magnetic susceptibility changes of fat /water like – tissues, perfusion..

↓

MRT not capable of substistuting Invasive/ Thermometry

(4): Odeen H. et al., Prog Nucl Magn Reson, 2019

Research topic and goals

- Research Topic :

Comprehensive analysis of the precision of Magnetic Resonance Thermometry during MR-guided deep-regional Hyperthermia Treatment (HT) of Soft-Tissue Sarcoma (STS)

- Research goals :

- Analysis of MRT temporal precision [4] during mild HT of STS (lower extremities, pelvic region)

- Impact of patient gross and gastrointestinal air motion induced errors on MRT precision

- Agreement of MRT precision in pre-treatment conditions (No heating) and during treatment

- Predictive power of similarity metrics (Jaccard [5], Average Haussdorf Distance) applied on internal air and patient anatomy changes throughout each treatment

- Increase in temperature degrades MRT precision by increasing intestinal air motion

(4): Feddersen. et al., Cancers, 2021,(5): Vilas-Boas Ribeiro et al, Cancers, 2021

Materials & Methods

LMU KLINIKUM

Hyperthermia treatment characteristics (From 2020 – 2022)		
Treatment region	Pelvis	Lower Extremities
Number of patients	16	16
Total number of sessions	81	120
Sessions per treatments	6 ± 4	7 ± 4
Duration (min) of each session	90 ± 2	90 ± 3
Double Scans per session	9 ± 1	9 ± 1
Maximum heating power (W)	770 ± 170	510 ± 190
Number of sessions with probes	26	12

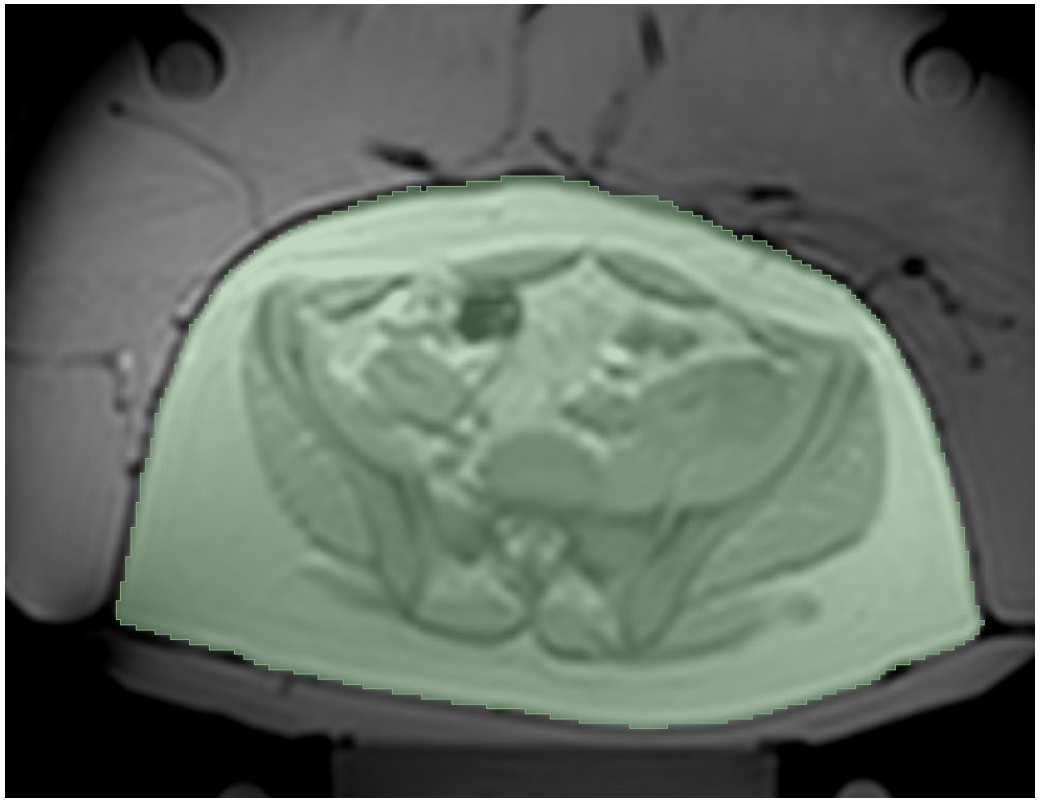
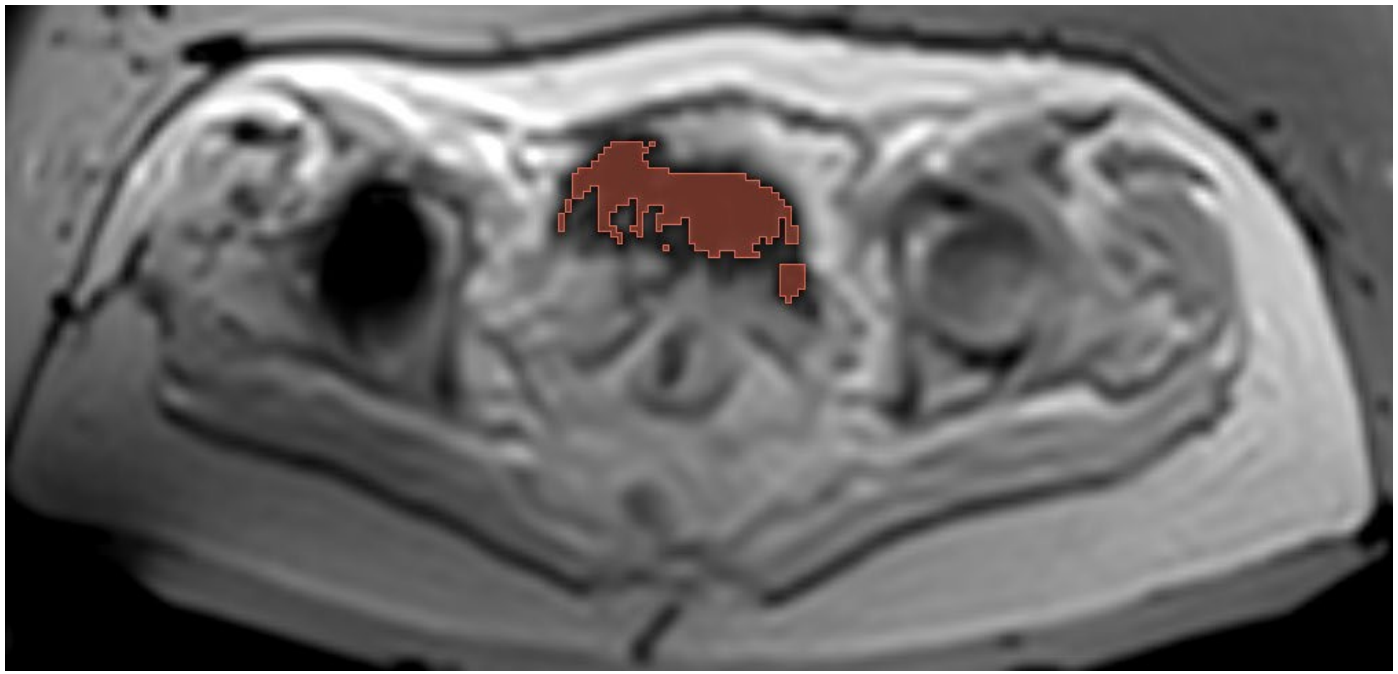
Masked MRT

Materials & Methods_Segmentation

LMU KLINIKUM

- Large amount of patient dataset → ≈18 MRI acquisitions or 25*18=450 slices / treatment
- Low spatial resolution of patient and air contours → Voxel size : (2 X 2 X 10)mm
- Manual contouring via 3D Slicer software → Total time / treatment : 6 h!





Materials & Methods_Segmentation

- Adopted automatic segmentation techniques for prostate cancer patients treated at MR-Linacs
- Developed 3D U-Net-based automatic segmentation of patient volumes, fat segmentation
- MONAI Label : Free & open source platform which facilitates AI-based annotation

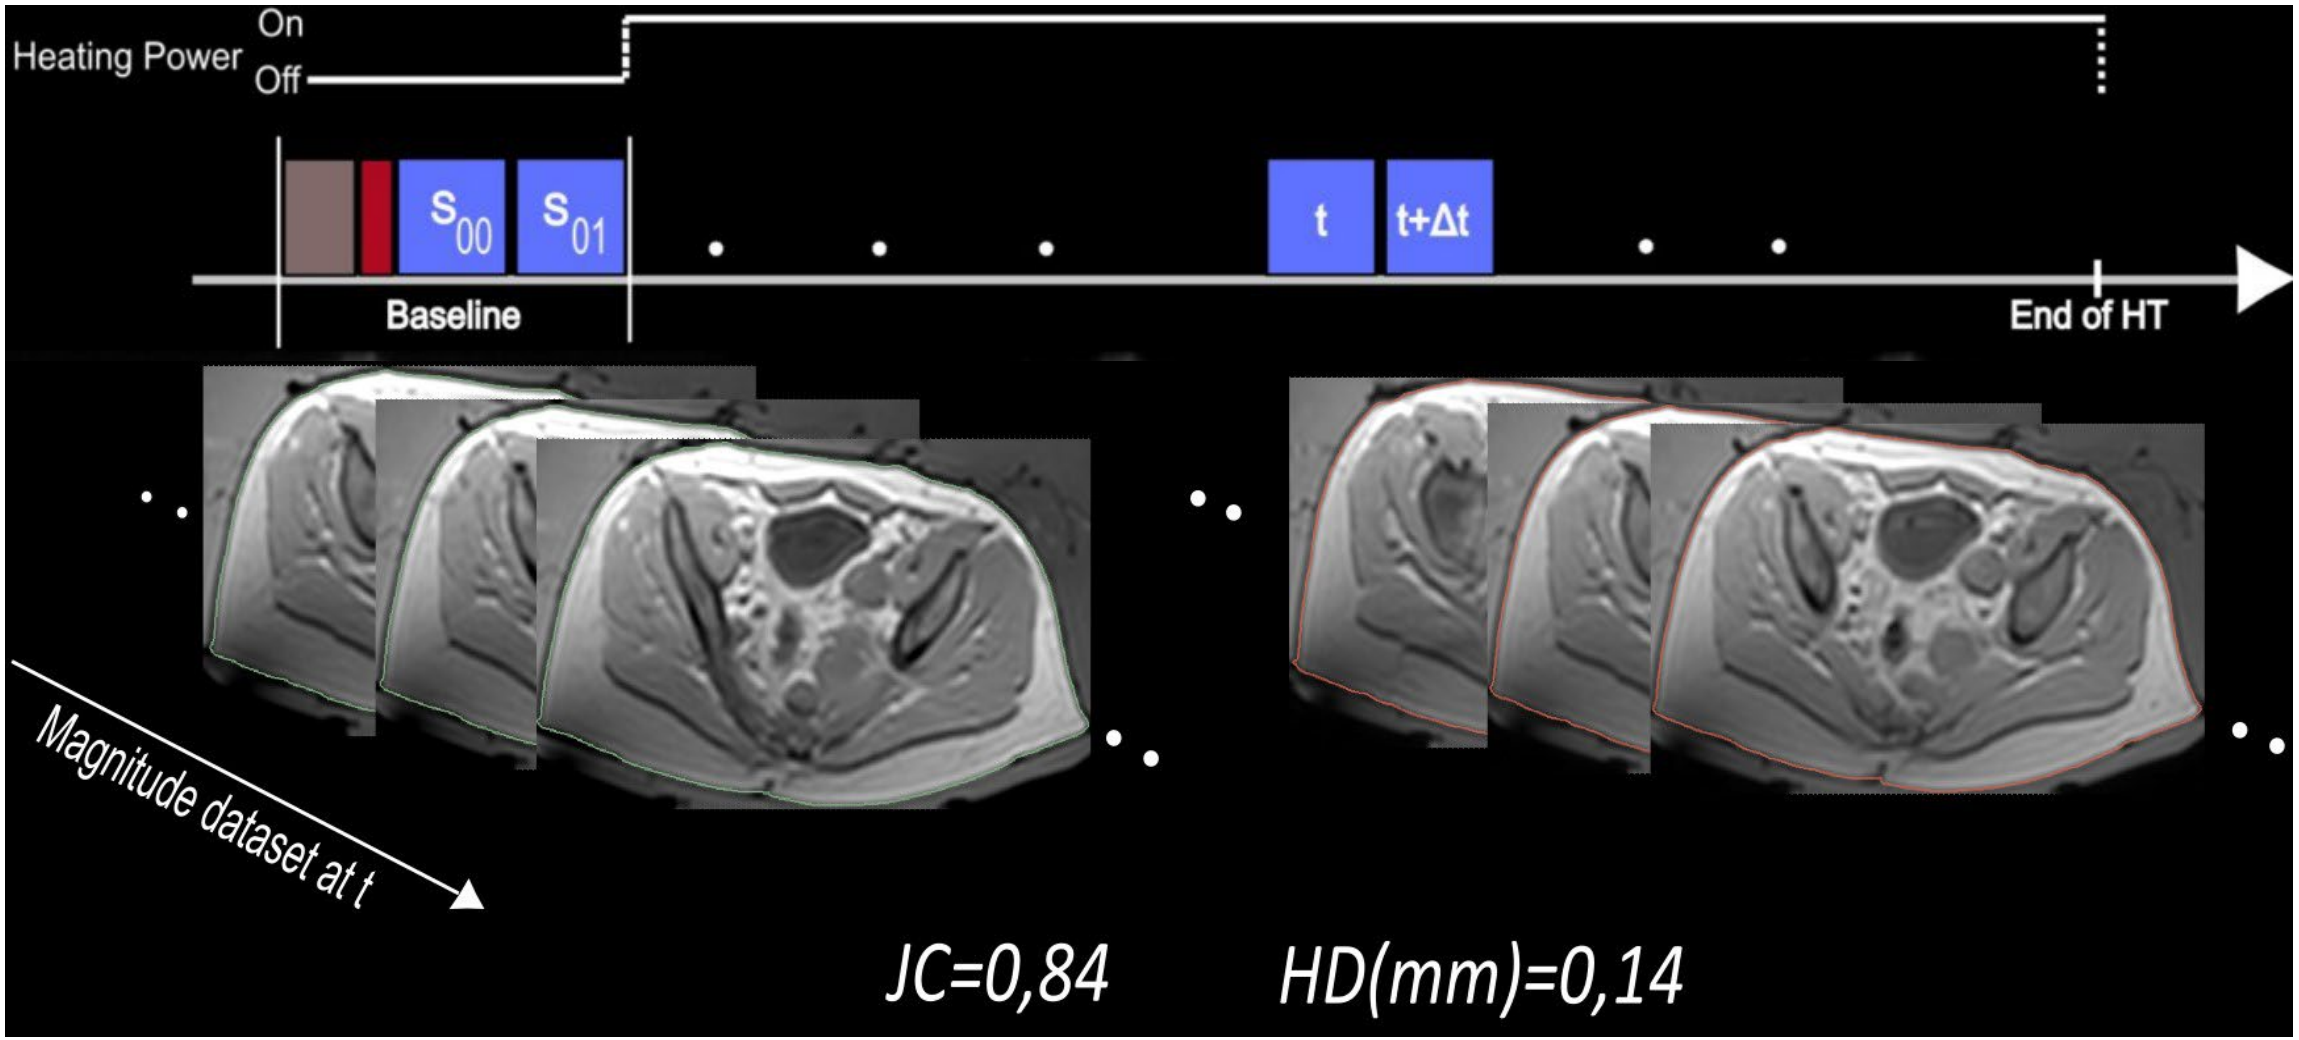
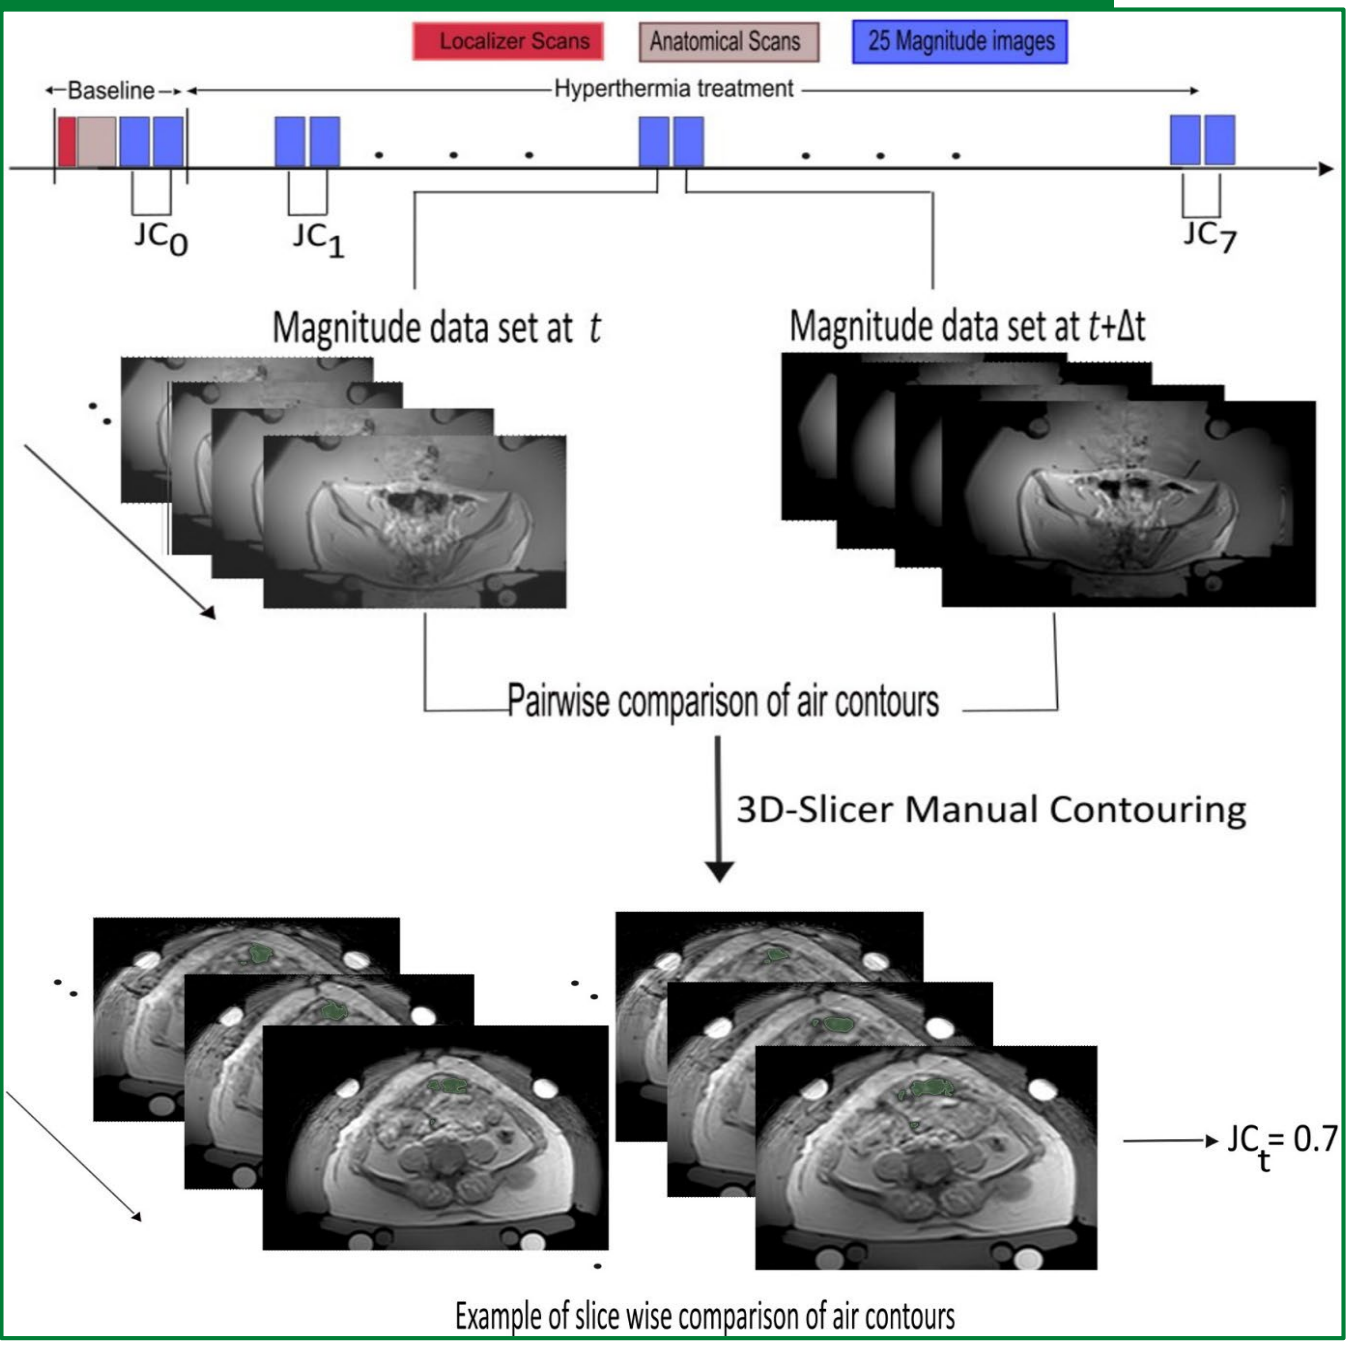
Patient motion during the treatment



Air motion during the treatment



$$JC_{baseline} = 0.5\ (0.1)$$

$$JC_{treatment} = 0.6\ (0.2)$$

Early results_ Calculation of MRT precision

	Offline processing		SigmaVision Software	
	Pelvis MAD/ σ	Lower Extremities MAD/σ	Pelvis MAD / σ	Lower Extremities MAD / σ
Baseline	0.3°C /0.8°C	0.1°C/0.4°C	0.3°C/ 0.9°C	0.2°C/0.6°C
Treatment	0.7°C /1.1°C	0.5°C/0.9°C	0.9°C /1.5°C	0.7°C/1.2°C

Mean TEM was always (0-0.1°C); Mean Absolute Deviation(MAD); standard deviation = σ;

(10): Vilas-Boas Ribeiro et al, AAPM, 2020

Future actions

- Segmentation masks of : Patients, air volumes, fat(?) using auto-segmentation algorithm and AI-assisted software MONAILabel

- Utility of patient masks for the correct calculation of MRT precision in baseline/treatment conditions

- MRT precision off-line post processing workflow VS SigmaVision Thermal maps

- ROC analysis for patient gross and gastrointestinal air-motion (for a larger patient dataset)

- Relation between air/patient motion similarity metrics VS MRT precision
